```

As can be seen from the highlighted route above the label stack, the route are the transport labels **958810** and **200066** on top (this is the ECMP label path to reach **NH 6.6.6.66**), with the **tenant-a** VPN label **958810** next in the stack, identifying the route as belonging to **tenant-a**.

As a comparison, look at the routes for **tenant-b**. As seen in the output, the VPN label assigned to **tenant-b** is **953372**.

```
north-edge# show bgp evpn route-type ip-prefix 100.10.11.0/24 detail

      MPLS label: 953372
north-edge#
```

If we now look at the routes in the VRF for **tenant-b**, we see that the VPN label has now changed, while the transport label (for **NH 6.6.6.66** is the same). The only difference seen in **tenant-b**, aside from the different VPN label, is that there are no host-routes in **tenant-b** because within each DC **tenant-b** is running in asymmetric mode; therefore, no host routes are generated/installed in the IP VRF.

```

18.17.4 EVPN VXLAN IPv6 Overlay

Beginning with *EOS Release 4.22.0F*, the EVPN VXLAN L3 Gateway using EVPN IRB supports routing traffic from one IPv6 host to another IPv6 host on a stretched VXLAN VLAN.

18.17.5 IP VPNs Sample Configuration

Here, we examine BGP EVPN layer 3 VPN over an LDP, ISIS-SR, and BGP-SR transport LSPs. This highlights the separation between the transport and the VPN overlay service.

The following figures illustrate the sample VPN Physical Topology.

Figure 18-63: IPv4 VPN Physical Topology

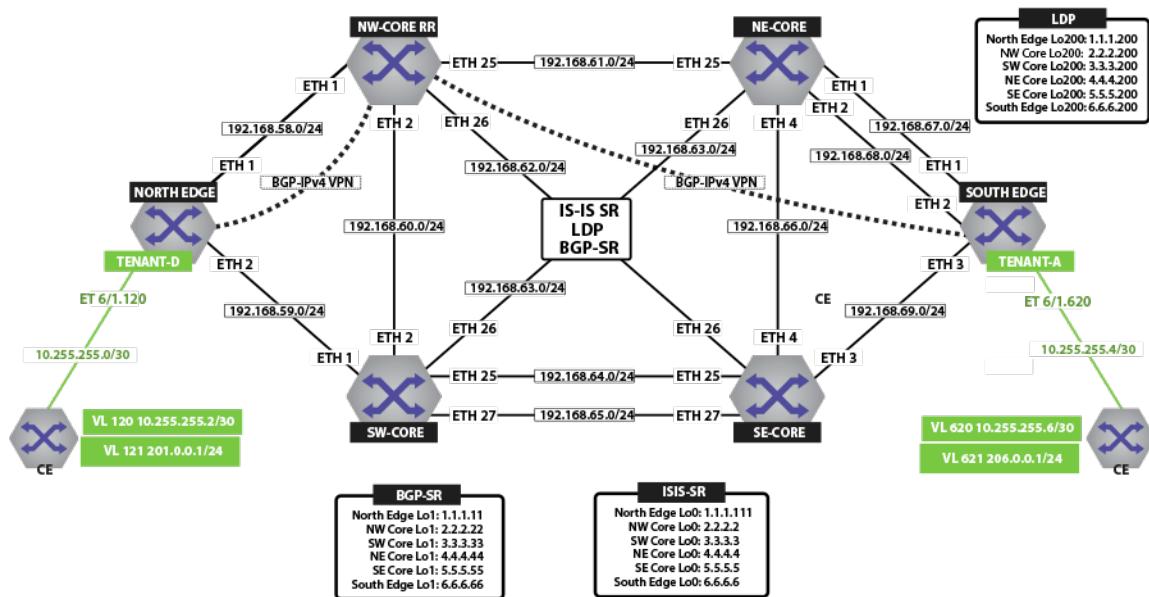

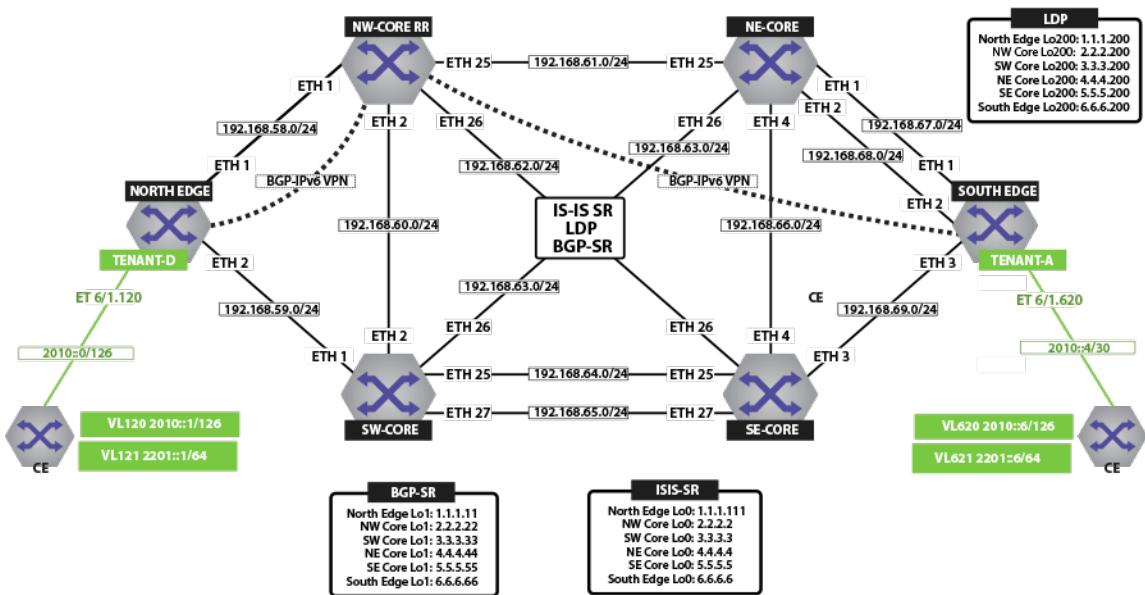

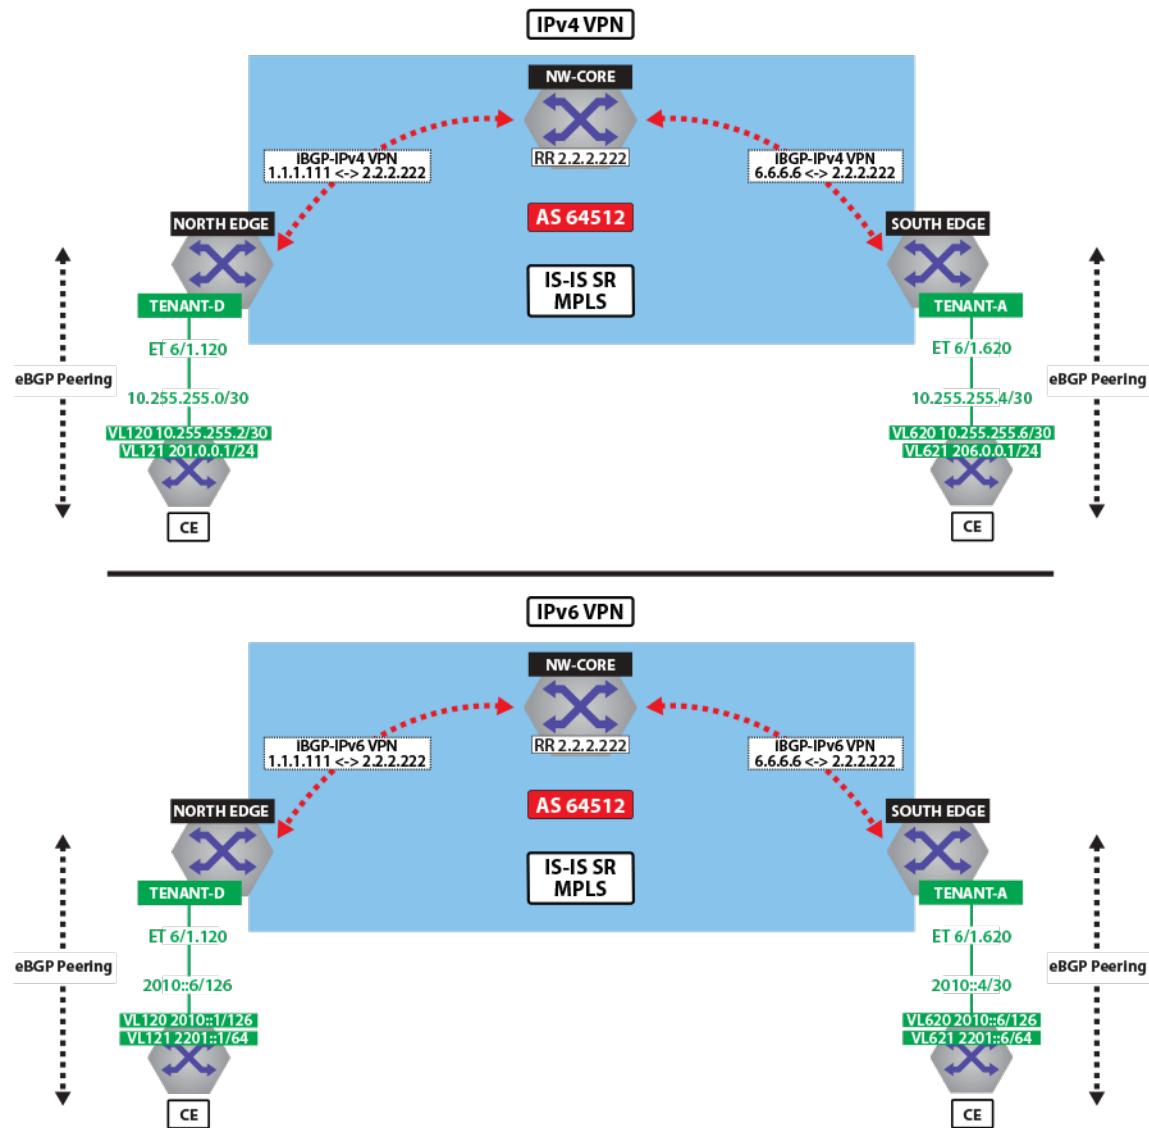

Figure 18-64: IPv6 VPN Physical Topology

18.17.5.1 IP VPN over ISIS-SR

The following figure illustrates an overview of the combined control and data planes.

Figure 18-65: IPv4 VPN and IPv6 VPN Over ISIS-SR MPLS

The next two figures illustrate the forwarding path and control plane for both IP traffic over ISIS-MPLS segment routing.

Figure 18-66: IPv4 VPN Forwarding Over ISIS-SR MPLS

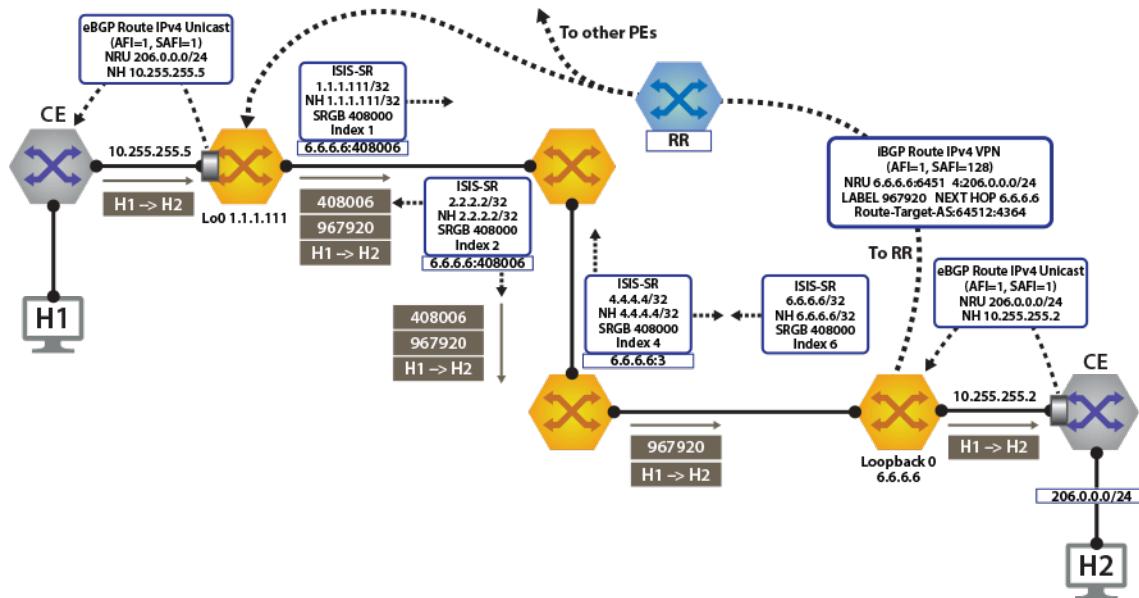

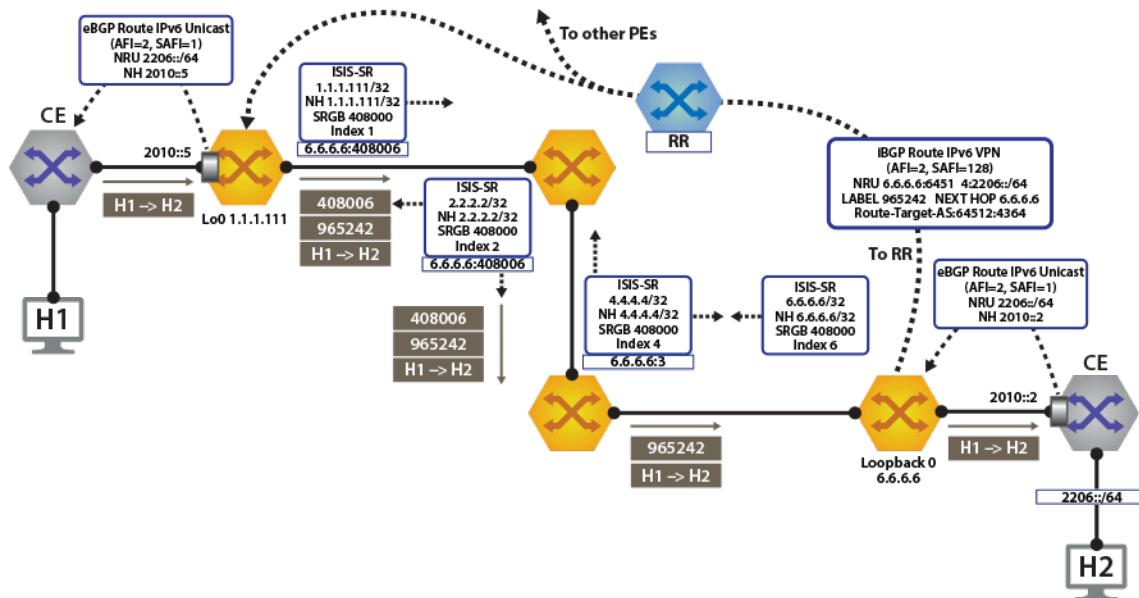

Figure 18-67: IPv6 VPN Forwarding Over ISIS-SR MPLS

View IPv4 and IPv6 Routes in the VRF

North Edge and South Edge routers have an eBGP peering session out to the CE; and learning routes from CE and remote PE.

- The `show ip route vrf tenant-d` command displays IPv4 Routes in the VRF of North Edge.

```
north-edge# show ip route vrf tenant-d
VRF: tenant-d
Codes: C - connected, S - static, K - kernel,
```

```

Activating IP VPN

In all scenarios, the IP VPN must be activated under BGP and neighbors configured to exchange the IP VPN NLRIs. The tenant's VRF (tenant-d) is associated with a dynamically assigned label by BGP.

North Edge

```

service routing protocols model multi-agent

router bgp 64512
    router-id 1.1.1.111
    maximum-paths 128 ecmp 128
    neighbor 2.2.2.222 remote-as 64512
    neighbor 2.2.2.222 update-source Loopback0
    neighbor 2.2.2.222 bfd
    neighbor 2.2.2.222 send-community extended
    neighbor 2.2.2.222 maximum-routes 12000
!
address-family vpn-ipv4
    neighbor 2.2.2.222 activate
    neighbor default encapsulation mpls next-hop-self source-interface Loopback0
!
address-family vpn-ipv6
    neighbor 2.2.2.222 activate
    neighbor default encapsulation mpls next-hop-self source-interface Loopback0
!
```

South Edge

```

service routing protocols model multi-agent

router bgp 64512
    router-id 6.6.6.6
    maximum-paths 128 ecmp 128
    neighbor 2.2.2.222 remote-as 64512
    neighbor 2.2.2.222 update-source Loopback0
    neighbor 2.2.2.222 bfd
    neighbor 2.2.2.222 send-community extended
    neighbor 2.2.2.222 maximum-routes 12000
!
address-family vpn-ipv4
    neighbor 2.2.2.222 activate
    neighbor default encapsulation mpls next-hop-self source-interface Loopback0
!
address-family vpn-ipv6
    neighbor 2.2.2.222 activate
    neighbor default encapsulation mpls next-hop-self source-interface Loopback0
!
```

The configuration above provides the following:

- It enables the multi-agent routing protocol model, which is required for BGP VPN support.
- It sets the local autonomous system number to **64512** and configured the route-reflector for both IPv4 VPN and IPv6 VPN capabilities.
- It sets the IP VPN encapsulation type to MPLS (default).

- It specifies that **Loopback0** will be used as the next-hop for all advertised VPN routes. The underlay configuration must provide MPLS LSPs from remote PEs to this loopback interface address.

Layer 3 Overlay Configuration

Distribution of Layer 3 routes over BGP is enabled by configuring one or more IP VRFs under the router bgp configuration mode. Additionally, either IPv4 or IPv6 routing must be enabled in the VRF.

- Configure IP VRF in the North Edge router.

```
vrf instance tenant-d
ip routing vrf tenant-d
ipv6 unicast-routing vrf tenant-d
!
router bgp 64512
vrf tenant-d
rd 1.1.1.1:64514
route-target import vpn-ipv4 64512:4364
route-target import vpn-ipv6 64512:4364
route-target export vpn-ipv4 64512:4364
route-target export vpn-ipv6 64512:4364
neighbor 10.255.255.6 remote-as 65011
neighbor 10.255.255.6 maximum-routes 12000
neighbor 2010::6 remote-as 65011
neighbor 2010::6 maximum-routes 12000
!
address-family ipv6
    neighbor 2010::6 activate
redistribute connected
!
```

- Configure IP VRF in the South Edge router.

```
vrf instance tenant-d
ip routing vrf tenant-d
ipv6 unicast-routing vrf tenant-d
!
router bgp 64512
vrf tenant-d
rd 6.6.6.6:64514
route-target import vpn-ipv4 64512:4364
route-target import vpn-ipv6 64512:4364
route-target export vpn-ipv4 64512:4364
route-target export vpn-ipv6 64512:4364
neighbor 10.255.255.2 remote-as 65010

These IP VRF configurations provide the following functionalities:

- It defines overlay VRFs (tenant-d) on the PE and enables IP unicast routing.
- The VRF is assigned a unique Route-Distinguisher (RD). The RD allows the PE to advertise VPN routes for the same IP prefix that have been exported by different VRFs. The NLRI RouteKey of a route exported from the VRFs IPv4 table into VPN consists of both the RD and the original IP prefix.
- The Route-Target (RT) extended communities for the VRF. The RTs are associated with all routes exported from the VRF. Received VPN routes carrying at least one RT matching the VRFs configuration are imported into the VRF.

Verifying IP VPNs over ISIS-SR

- The **show bgp vpn-ipv4 summary** command displays the status of the VPN IP peers in the North Edge router with the BGP VPN enabled.

```
north-edge# show bgp vpn-ipv4 summary
BGP summary information for VRF default
Router identifier 1.1.1.111, local AS number 64512
Neighbor Status Codes: m - Under maintenance
  Neighbor      V  AS          MsgRcvd  MsgSent  InQ  OutQ  Up/Down State

LST: 2.2.2.222
```

Note: Each entry in the table represents a BGP path. The path specific information includes the Route-Distinguisher and the IP prefix. Paths are either received from VPN peers or exported from local VRFs.

- The **show bgp vpn-ipv4 206.0.0.0/24 detail** and **show bgp vpn-ipv6 2206::/64 detail** commands display detailed view of the IP prefix route for **206.0.0.0/24** and **2206::/64** of the North Edge router.

```

north-edge# show bgp vpn-ipv4 206.0.0.0/24 detail
BGP routing table information for VRF default
Router identifier 1.1.1.111, local AS number 64512
BGP routing table entry for IPv4 prefix 206.0.0.0/24, Route Distinguisher: 6.6.6.6:64514
Paths: 1 available
 65010
    6.6.6.6 from 2.2.2.222 (2.2.2.222)
      Origin IGP, metric -, localpref 100, weight 0, valid, internal, best
      Extended Community: Route-Target-AS:64512:4364
      MPLS label: 967920

north-edge# show bgp vpn-ipv6 2206::/64 detail
BGP routing table information for VRF default
Router identifier 1.1.1.111, local AS number 64512
BGP routing table entry for IPv6 prefix 2206::/64, Route Distinguisher: 6.6.6.6:64514
Paths: 1 available
 65010
    6.6.6.6 from 2.2.2.222 (2.2.2.222)
      Origin IGP, metric -, localpref 100, weight 0, valid, internal, best
      Extended Community: Route-Target-AS:64512:4364
      MPLS label: 965242

```

Note: The output includes the RD and IP prefixes identifying the route. As seen in the output, the IPv4 VPN route is received from **2.2.2.222** because it is set-up to be a route-reflector, but the next hop is **6.6.6.6**. Both are advertised with tenant VPN label **967920** and **965242** and an RT.

- The **show ip bgp vrf tenant-d** command displays the BGP table for the VRF containing the imported EVPN routes.

```

north-edge# show ip bgp vrf tenant-d
BGP routing table information for VRF tenant-d
Router identifier 1.1.1.1, local AS number 64512
Route status codes: s - suppressed, * - valid, > - active, # - not installed, E - ECMP head, e - ECMP
                     S - Stale, c - Contributing to ECMP, b - backup, L - labeled-unicast
                     % - Pending BGP convergence
Origin codes: i - IGP, e - EGP, ? - incomplete

                    Network       Next Hop     Metric LocPref Weight Path
* >Ec 10.255.255.0/30 6.6.6.6      -      100    0   65010 i Or-ID: 6.6.6.6 C-LST: 2.2.2.222
* ec 10.255.255.0/30 6.6.6.6      -      100    0   65010 i Or-ID: 6.6.6.6 C-LST: 2.2.2.222
* > 10.255.255.4/30 10.255.255.6 -      100    0   65011 i
* > 201.0.0.0/24    10.255.255.6 -      100    0   65011 i
* >Ec 206.0.0.0/24   6.6.6.6      -      100    0   65010 i Or-ID: 6.6.6.6 C-LST: 2.2.2.222
* ec 206.0.0.0/24   6.6.6.6      -      100    0   65010 i Or-ID: 6.6.6.6 C-LST: 2.2.2.222

```

Note: Each entry in the table represent a BGP path that is either locally redistributed and received into the VRF or imported from the IPv4 VPN table. VPN routes are received from router **2.2.2.222** C-List (cluster list - basically identifying this route as from a route-reflector) with originating router being **6.6.6.6**.

Finally, let us look at the routes in the VRF tenant-d.

```

VRF: tenant-d
Codes: C - connected, S - static, K - kernel,
       O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
       E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
       N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP,
       R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
       O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
       NG - Nexthop Group Static Route, V - VXLAN Control Service,
       DH - DHCP client installed default route, M - Martian,
       DP - Dynamic Policy Route

Gateway of last resort is not set

```

```

B I      10.255.255.0/30 [200/0] via 6.6.6.6/32, IS-IS SR tunnel index 6, label 967920
          via 192.168.58.12, Ethernet1/1, label 408006
C       10.255.255.4/30 is directly connected, Ethernet6/1.120
B E      201.0.0.0/24 [200/0] via 10.255.255.6, Ethernet6/1.120
B I      206.0.0.0/24 [200/0] via 6.6.6.6/32, IS-IS SR tunnel index 6, label 967920
          via 192.168.58.12, Ethernet1/1, label 408006

```

 **Note:** As displayed in the highlighted route above the label stack, the route is the transport label **408006** on top (this is the label to reach **NH 6.6.6.6**), with the **tenant-a** VPN label **967920** next in the stack, identifying the route as belonging to **tenant-d**.

A check of the Tunnel FIB confirms that **408006** is the ISIS-SR LSP.

```

north-edge# show mpls tunnel fib
! 'show mpls tunnel fib' has been deprecated. Please use 'show tunnel fib [options]' moving forward.

18.17.5.2 IP VPNs Over LDP

The following figures illustrate an overview of the combined control and data planes.

Figure 18-68: IPv4 VPN and IPv6 VPN Over LDP MPLS

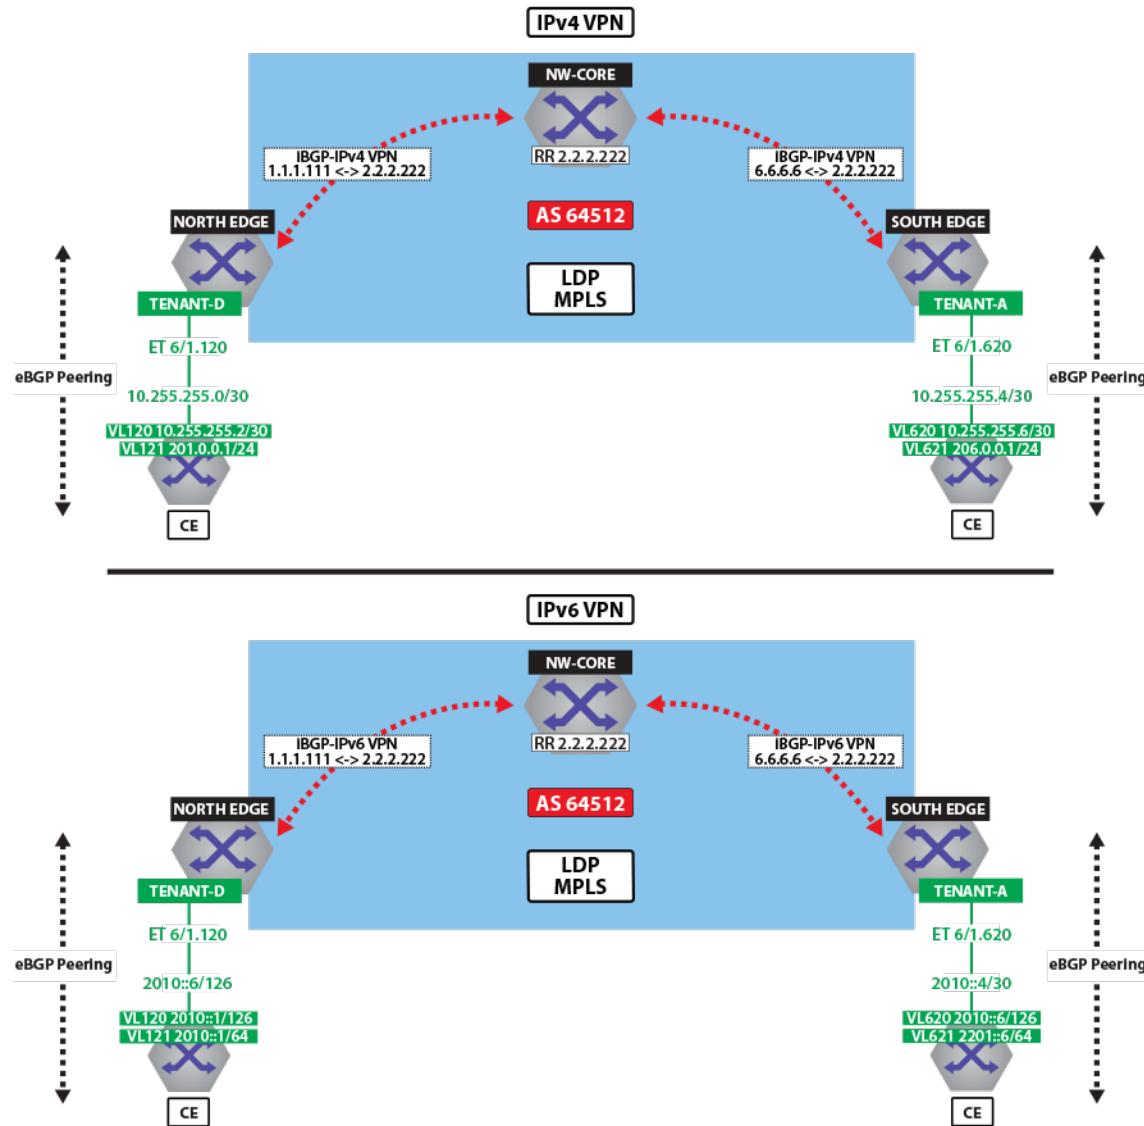

Figure 18-69: IPv4 VPN Forwarding Over LDP MPLS

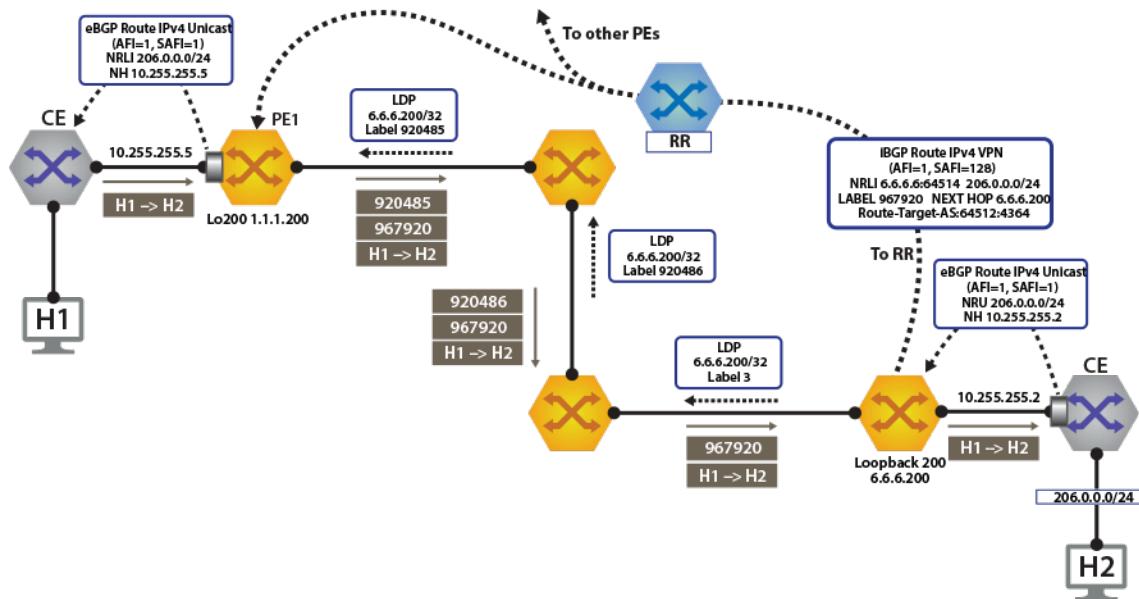

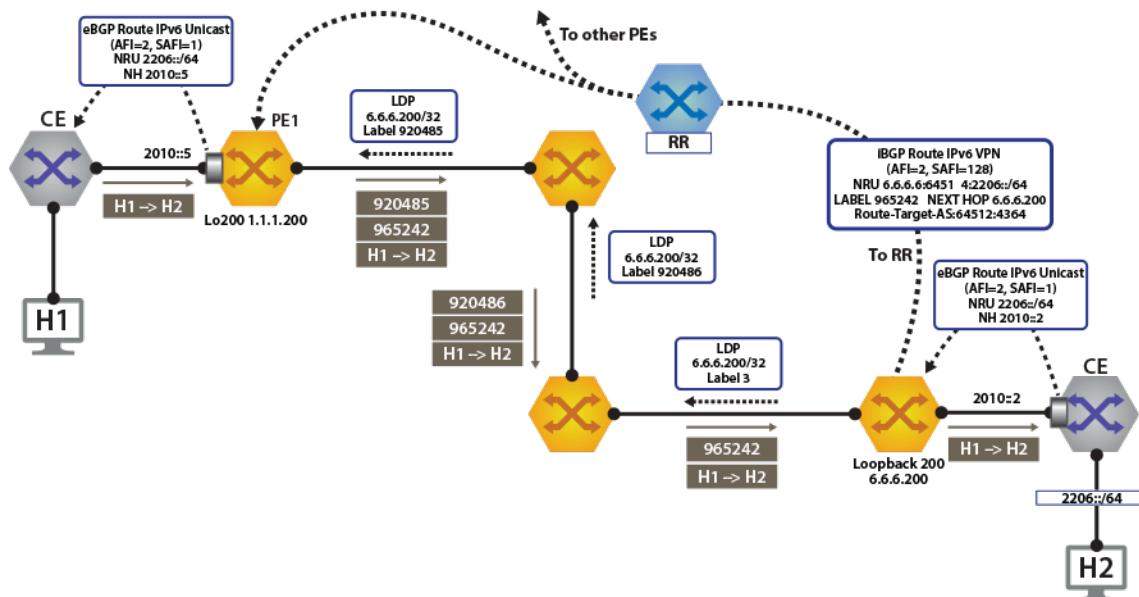

Figure 18-70: IPv6 VPN Forwarding Over LDP MPLS

To switch to using the MPLS LDP transport, we just need to change the next-hop we advertised for the VPN routes. As shown, the next hop needs to be set to **loopback 200** for using the LDP LSP.

This is achieved by configuring the next-hop for the EVPN routes on both north and south edge routers.

```
router bgp 64512
!
address-family evpn
    neighbor default encapsulation mpls next-hop-self source-interface Loopback200
```

After this is configured, check the BGP updates and the routes in the VRF. The output again includes the RD and IP prefix identifying the route. Now the NH is set to **6.6.6.200** for **tenant-d**.

```
north-edge# show bgp vpn-ipv4 206.0.0.0/24 detail
BGP routing table information for VRF default
Router identifier 1.1.1.111, local AS number 64512
BGP routing table entry for IPv4 prefix 206.0.0.0/24, Route Distinguisher: 6.6.6.6:64514
Paths: 1 available
 65010
    6.6.6.200 from 2.2.2.222 (2.2.2.222)
      Origin IGP, metric -, localpref 100, weight 0, valid, internal, best
      Extended Community: Route-Target-AS:64512:4364
      MPLS label: 967920
north-edge#
north-edge# show bgp vpn-ipv6 2206::/64 detail
BGP routing table information for VRF default
Router identifier 1.1.1.111, local AS number 64512
BGP routing table entry for IPv6 prefix 2206::/64, Route Distinguisher: 6.6.6.6:64514
Paths: 1 available
 65010
    6.6.6.200 from 2.2.2.222 (2.2.2.222)
      Origin IGP, metric -, localpref 100, weight 0, valid, internal, best
      Extended Community: Route-Target-AS:64512:4364
      MPLS label: 965242
north-edge#
```

Note: The VPN label has not changed from the ISIS-SR case above (**967920** and **965242**), reinforcing the fact that the BGP VPN label is orthogonal to the transport label.

```
north-edge# show ip route vrf tenant-d
VRF: tenant-d
Codes: C - connected, S - static, K - kernel,
       O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
       E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
       N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP,
       R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
       O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
       NG - Nexthop Group Static Route, V - VXLAN Control Service,
       DH - DHCP client installed default route, M - Martian,
       DP - Dynamic Policy Route

Gateway of last resort is not set

      B I      10.255.255.0/30 [200/0] via 6.6.6.200/32, LDP tunnel index 1, label 967920
                                         via 192.168.58.12, Ethernet1/1, label 904097
      C      10.255.255.4/30 is directly connected, Ethernet6/1.120
      B E     201.0.0.0/24 [200/0] via 10.255.255.6, Ethernet6/1.120
      B I     206.0.0.0/24 [200/0] via 6.6.6.200/32, LDP tunnel index 1, label 967920
                                         via 192.168.58.12, Ethernet1/1, label 904097

north-edge(config-router-bgp)# show ipv6 route vrf tenant-d
```

```
VRF: tenant-d
Displaying 4 of 7 IPv6 routing table entries
Codes: C - connected, S - static, K - kernel, O3 - OSPFv3, B - BGP, R - RIP, A B - BGP Aggregate,
I L1 - IS-IS level 1, I L2 - IS-IS level 2, DH - DHCP, NG - Nexthop Group Static Route,
M - Martian, DP - Dynamic Policy Route

      B     2010::/126 [200/0]
            via 6.6.6.32, IS-IS SR tunnel index 6, label 965242
            via 192.168.58.12, Ethernet1/1, label 408006
      C     2010::4/126 [0/0]
            via Ethernet6/1.120, directly connected
      B     2201::/64 [200/0]
            via 2010::6, Ethernet6/1.120
      B     2206::/64 [200/0]
            via 6.6.6.32, IS-IS SR tunnel index 6, label 965242
            via 192.168.58.12, Ethernet1/1, label 408006
```

Note: As seen from the highlighted route above the label stack, the route are the transport label **904097** on top (this is the label path to reach **NH 6.6.6.200**), with the **tenant-d** VPN label **967920** next in the stack, and identifying the route as belonging to **tenant-a**.

A capture of the dataplane on North-Edge matching on the LDP transport label confirms the encapsulated traffic on the wire. **904097:967920:[Source IP Address][Destination IP Address]**.

18.17.5.3 IP VPNs Over BGP-SR

The following figures illustrate an overview of the combined control and data planes.

Figure 18-71: IPv4 VPN and IPv6 VPN Over BGP-SR MPLS

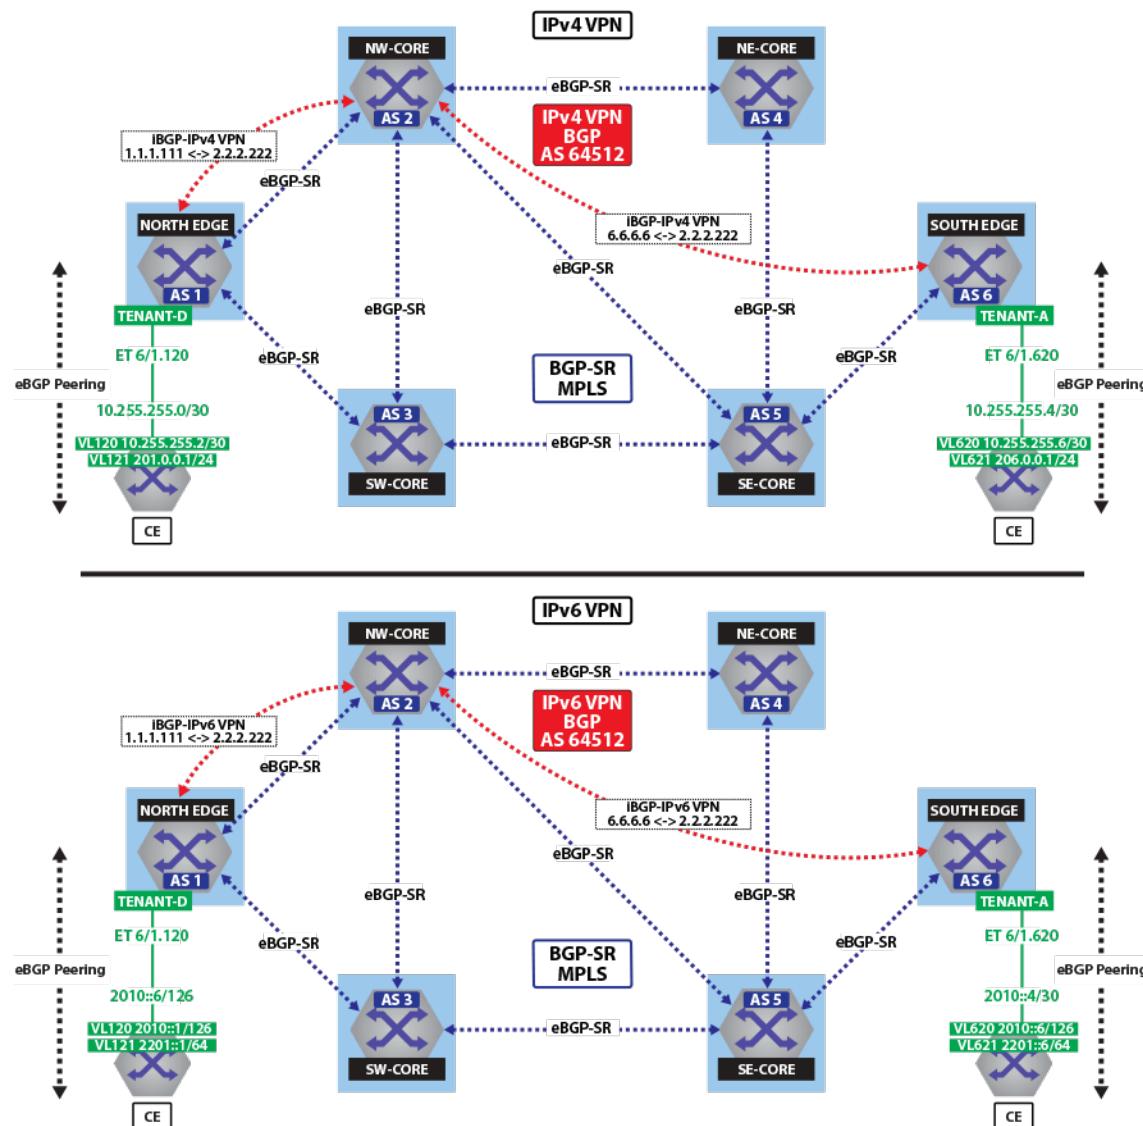

Figure 18-72: IPv4 VPN Forwarding Over BGP-SR MPLS

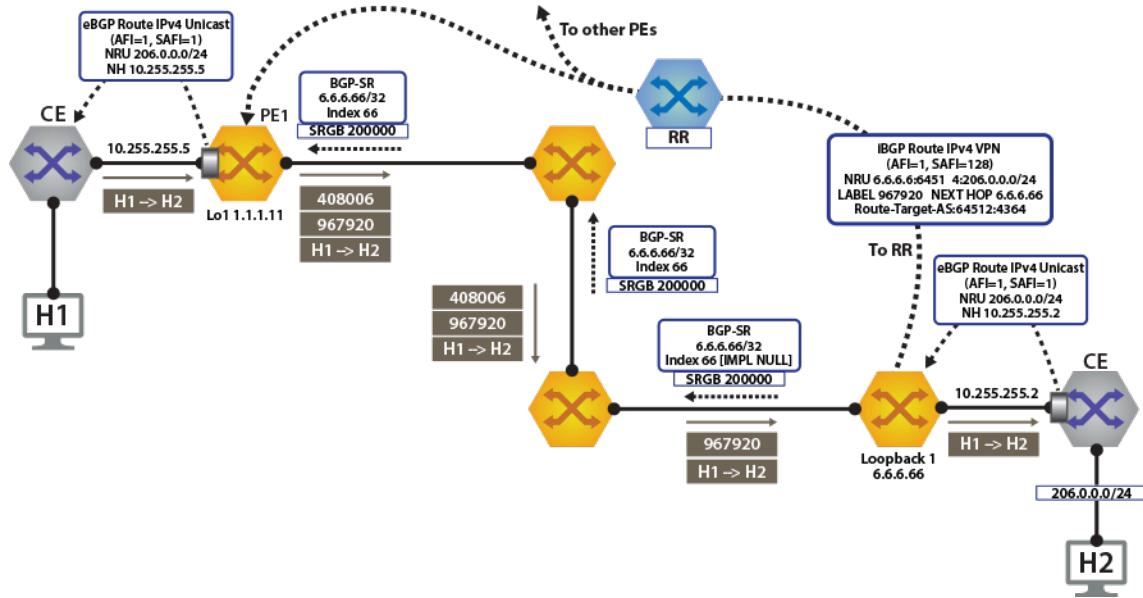

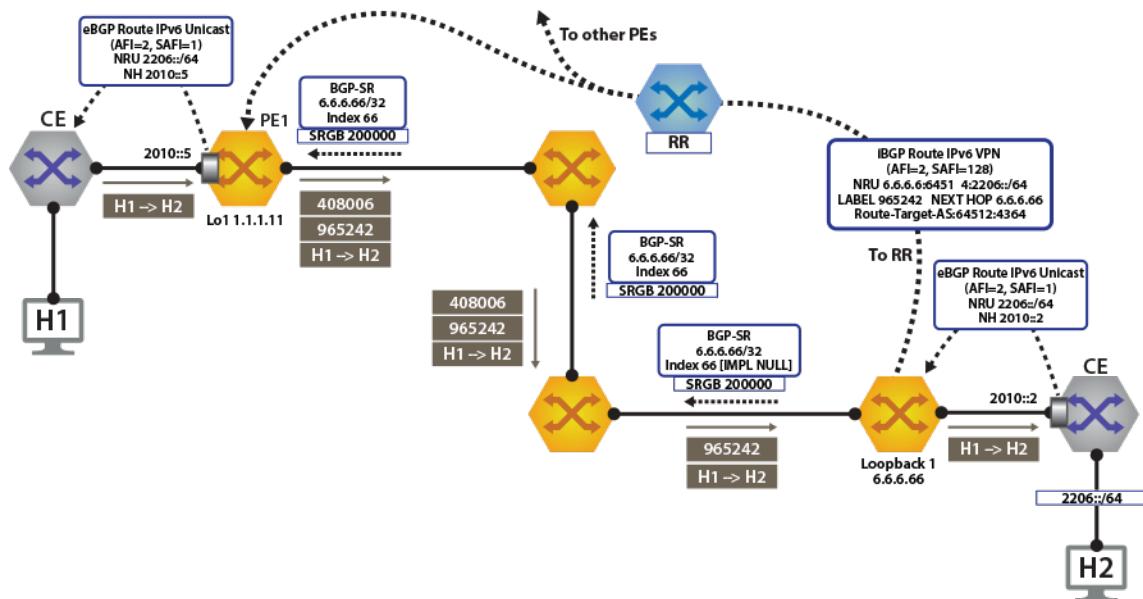

Figure 18-73: IPv6 VPN Forwarding Over BGP-SR MPLS

To switch to using the MPLS BGP-SR transport, we just need to change the next-hop we advertised for the VPN routes. As shown, the next hop needs to be set to **loopback 1** for using the BGP-SR LSP.

This is achieved by configuring the next-hop for EVPN routes.

```
router bgp 64512
!
address-family evpn
    neighbor default encapsulation mpls next-hop-self source-interface
        Loopback1
```

Once this is configured, we can check the BGP updates and the routes in the VRF. The output again includes the RD and IP prefix identifying the route. As seen in the output, we now have the NH set to **6.6.6.66** for **tenant-d**.

```
north-edge# show bgp vpn-ipv4 206.0.0.0/24 detail

BGP routing table information for VRF default
Router identifier 1.1.1.111, local AS number 64512
BGP routing table entry for IPv6 prefix 2206::/64, Route Distinguisher: 6.6.6.6:64514
Paths: 1 available
 65010
    6.6.6.66 from 2.2.2.222 (2.2.2.222)
      Origin IGP, metric -, localpref 100, weight 0, valid, internal, best
      Extended Community: Route-Target-AS:64512:4364
      MPLS label: 965242
north-edge#
```

Note: The VPN label has not changed from the ISIS-SR case above (**967920** and **965242**), reinforcing the fact that the BGP VPN label is orthogonal to the transport label.

The output again includes the RD and IP prefix identifying the route. As seen in the output, we now have the NH set to **6.6.6.66** for **tenant-d**.

```
north-edge# show bgp vpn-ipv4 206.0.0.0/24 detail
BGP routing table information for VRF default
Router identifier 1.1.1.111, local AS number 64512
BGP routing table entry for IPv4 prefix 206.0.0.0/24, Route Distinguisher: 6.6.6.6:64514
Paths: 1 available
 65010
    6.6.6.66 from 2.2.2.222 (2.2.2.222)
      Origin IGP, metric -, localpref 100, weight 0, valid, internal, best
      Extended Community: Route-Target-AS:64512:4364
      MPLS label: 967920
north-edge#
north-edge# show bgp vpn-ipv6 2206::/64 detail
BGP routing table information for VRF default
Router identifier 1.1.1.111, local AS number 64512
BGP routing table entry for IPv6 prefix 2206::/64, Route Distinguisher: 6.6.6.6:64514
Paths: 1 available
 65010
    6.6.6.66 from 2.2.2.222 (2.2.2.222)
      Origin IGP, metric -, localpref 100, weight 0, valid, internal, best
      Extended Community: Route-Target-AS:64512:4364
      MPLS label: 965242
north-edge#
```

Note: The VPN label has not changed from the ISIS-SR case above (**967920** and **965242**), reinforcing that the BGP VPN label is orthogonal to the transport label.

As displayed in the highlighted route above the label stack, the route are the transport label **200066** on top (this is the label path to reach **NH 6.6.6.66**), with the **tenant-d** VPN label **967920** next in the stack, and identifying the route as belonging to **tenant-a**.

18.18 EVPN and VCS Commands

Global Configuration Mode

- `router general`

Router BGP Configuration Mode

- `next-hop resolution disabled`
- `redistribute service vxlan`
- `route-target`
- `route-target export`
- `route-target import`
- `route-target route-map`
- `vlan` (VLAN-AWARE-Bundle configuration mode)
- `vni-aware-bundle`

Router BGP Address-Family Configuration Mode

- `encapsulation vxlan layer-3 set next-hop igr-cost`

Router General Configuration Mode

- `leak routes`
- `router multicast vrf leak`

VCS Commands

- `redistribute bgp evpn vxlan`

EVPN VXLAN Commands

- `bfd vtep evpn`
- `redistribute router-mac next-hop vtep primary`

E-Tree Commands

- `e-tree`
- `remote leaf host drop`
- `show e-tree vlan`

Display Commands

- `show bgp evpn`
- `show e-tree vlan`
- `show ip bgp vrf`
- `show ip route vrf`
- `show ipv6 bgp vrf`
- `show ipv6 route vrf`

-
- show l2rib input all
 - show l2Rib input VXLAN-control-service
 - show l2rib output
 - show service vxlan address-table
 - show vrf leak flapping
 - show VXLAN control-plane

18.18.1 bfd vtep evpn

The **bfd vtep evpn** command to configure the BGP PIC Edge for EVPN VXLAN routes for remote VTEPs. This command is configured under the VXLAN Tunnel Interface (VTI).

The **no bfd vtep evpn** command removes bfd vtep evpn configuration from the *running-config*.

Command Mode

VXLAN Tunnel Interface (VTI) Mode

Command Syntax

```
bfd vtep evpn interval interval-milliseconds min-rx min-rx-milliseconds multiplier multiplier-range
no bfd vtep evpn interval interval-milliseconds min-rx min-rx-milliseconds multiplier multiplier-range
```

Parameters

- **interval** Set transmit rate in milliseconds.
 - ***interval-milliseconds*** Rate in milliseconds. Value ranges from **50** to **60000** milliseconds.
- **min-rx** Set expected minimum incoming rate in milliseconds.
 - ***min-rx-milliseconds*** Rate in milliseconds. Value ranges from **50** to **60000** milliseconds.
- **multiplier** Sets the BFD multiplier.
 - ***multiplier-range*** The value ranges from **3** to **50**.

Example

In this example (assuming symmetric configuration on other PE devices) any BFD for VXLAN session initiated on the VTI would have a detect time of **300ms** (interval of 100ms multiplied by 3).

```
switch(config-if-Vx1)# bfd vtep evpn interval 100 min-rx 100 multiplier 3
```

18.18.2 encapsulation VXLAN layer-3 set next-hop igr-cost

The `encapsulation VXLAN layer-3 set next-hop igr-cost` command configures the underlay IGP metric for the VTEP reachability to be considered for BGP best path selection in the IP VRF that is importing the EVPN route.

The `no encapsulation VXLAN layer-3 set next-hop igr-cost` or `default encapsulation VXLAN layer-3 set next-hop igr-cost` command removes all the IGP cost for VTEP running configurations on the switch.

Command Mode

BGP Address-Family Configuration

Command Syntax

```
encapsulation VXLAN layer-3 set next-hop igr-cost  
no encapsulation VXLAN layer-3 set next-hop igr-cost  
default encapsulation VXLAN layer-3 set next-hop igr-cost
```

Example

The following command configures the IGP cost for VTEP feature on the switch :

```
switch(config-router-bgp) # address-family evpn  
switch(config-router-bgp-af) # [no | default] encapsulation VXLAN layer-3 set next-hop igr-cost
```

18.18.3 e-tree

The **vlan e-tree** places the switch in VLAN configuration mode and allows configuration of E-Tree. By default, all VLANs have the E-Tree root role. Use the **no e-tree role leaf** to set the VLAN to the default role, **root**.

Command Mode

VLAN Configuration Mode

Command Syntax

[vlan *vlan_id*] e-tree role leaf

Parameters

- **vlan *vlan_id*** - Specify the VLAN to configure E-Tree.
- **role** - Specify the role of the VLAN.
- **leaf** - Specify the role as leaf.

Examples

- Use the following command to set **VLAN 100** as an E-Tree leaf role:

```
switch(config)# vlan 100
switch(config-vlan-100) # e-tree role leaf
```

- To return the VLAN to the E-tree role **root**, use the following command:

```
switch(config)# vlan 100
switch(config-vlan-100) # no e-tree role leaf
```

18.18.4 leak routes

The **leak routes** command configures an inter-VRF route-leaking policy to allow routes to be leaked from one VRF to another using a route map.

The **no leak routes** and **default leak routes** commands remove the specified route-leaking policy from *running-config*.

Command Mode

Router General Configuration

Command Syntax

```
leak routes source-vrf source_name subscribe-policy route_map  
no leak routes source-vrf source_name  
default leak routes source-vrf source_name
```

Example

These commands configure routes to be leaked from VRF **VRF1** to VRF **VRF2** according to the policy described in route-map **RM1**.

```
switch(config)# router general  
switch(config-router-general)# vrf VRF2  
switch(config-router-general-vrf-VRF2)# leak routes source-vrf VRF1 subscribe-policy RM1  
switch(config-router-general-vrf-VRF2)# exit  
switch(config-router-general)# exit  
switch(config)#
```

18.18.5 next-hop resolution disabled

The **next-hop resolution disabled** command disables the next-hop resolution in routes received from BGP-EVPN peers.

The **no next-hop resolution disabled** and the **default next-hop resolution disabled** commands enable the next-hop resolution in routes received from BGP-EVPN peers.

Command Mode

Router-BGP Address-Family Configuration

Command Syntax

next-hop resolution disabled

Example

This command disables the next-hop resolution in routes received from BGP-EVPN peers.

```
switch(config)# router bgp 65002
switch(config-router-bgp)# address-family evpn
switch(config-router-bgp-af)# next-hop resolution disabled
switch(config-router-bgp-af) #
```

18.18.6 redistribute bgp evpn VXLAN

The **redistribute bgp evpn VXLAN** command enables BGP-EVPN routes to be redistributed to VCS, which in turn advertises them to all VTEPs within the DC.

The **no redistribute bgp evpn VXLAN** and the **default redistribute bgp evpn VXLAN** commands disable the redistribution of BGP-EVPN routes to VCS.

Command Mode

CVX-VXLAN Configuration

Command Syntax

```
redistribute bgp evpn VXLAN
```

Example

This command enables redistribution of BGP-EVPN routes to VCS.

```
switch(config)# cvx
switch(config-cvx)# no shutdown
switch(config-cvx)# service VXLAN
switch(config-cvx-VXLAN)# no shutdown
switch(config-cvx-VXLAN)# redistribute bgp evpn VXLAN
```

18.18.7 redistribute router-mac next-hop vtep primary

Use the **redistribute router-mac next-hop vtep primary** command in the MAC VRF configuration mode to advertise an EVPN type-2 route for the VARP MAC with a nexthop of the primary VTEP IP.

Configuration Mode

MAC VRF

Command Syntax

```
redistribute router-mac next-hop vtep primary [router-mac | next-hop | vtep | primary]
```

Parameters

- **router-mac** Router Ethernet address.
- **next-hop** Configure the advertised next-hop.
- **vtep** Associate next-hop with a VTEP.
- **primary** Use the primary VTEP IP.

Example

The following example uses the command **redistribute router-mac next-hop vtep primary** in the MAC VRF configuration.

```
switch(config)# router bgp 65003
switch(config-router-bgp-65003)# neighbor 223.255.255.1 remote-as 65001
switch(config-router-bgp-65003)# neighbor 223.255.255.2 remote-as 65002
switch(config-router-bgp-65003)# neighbor 223.255.255.4 remote-as 65003

switch(config)# vlan 100
switch(config-vlan-100)# rd 1:100
switch(config-vlan-100-rd-100)# route-target both 1:100
switch(config-vlan-100-rd-100)# redistribute learned
switch(config-vlan-100-rd-100)# redistribute router-mac next-hop vtep primary

switch(config)# vlan 200
switch(config-vlan-200)# rd 1:200
switch(config-vlan-100-rd-200)# route-target both 1:200
switch(config-vlan-100-rd-200)# redistribute learned
switch(config-vlan-100-rd-200)# redistribute router-mac next-hop vtep primary
```

18.18.8 redistribute service VXLAN

The **redistribute service VXLAN** command enables BGP to redistribute the Layer 2 bridging information received from VCS.

The **no redistribute service VXLAN** and the **default redistribute service VXLAN** commands disable the redistribution of the bridging information received from VCS.

Command Mode

Router-BGP VNI Configuration

Command Syntax

```
redistribute service VXLAN
```

Example

This command enables redistribution of the Layer 2 bridging information received from VCS.

```
switch(config)# router bgp 100
switch(config-router-bgp)# vni-aware-bundle bundle1
switch(config-macvrf-bundle1)# redistribute service VXLAN
```

18.18.9 remote leaf host drop

The `remote leaf host drop` command allows the configuration of per-VLAN explicit drop routes for E-Tree.

Command Mode

VLAN E-Tree Configuration Mode

Command Syntax

```
remote leaf host drop
```

Example

Use the following commands to configure per-VLAN explicit drop routes for VLAN 100:

```
switch(config)#vlan 100
switch(config-vlan-100)#e-tree role leaf
    switch(config-vlan-etree-100)#remote leaf host drop
```

18.18.10 route-target

The **route-target** command configures a well-known extended community that is used by BGP-EVPN to export routes from or import routes into MAC-VRF.

The **no route-target** and **default route-target** commands delete the route-target configuration.

Command Mode

Router-BGP VNI Configuration

Syntax

```
route-target [export | import | both] rt  
no route-target  
default route-target
```

Parameters

- **export** configures a well-known extended community that is attached to the routes exported by BGP-EVPN.
- **import** configures a well-known extended community that identifies the received routes that need to be imported into the MAC-VRF specified by the VNI bundle.
- **both** configures the same extended community for import and export of routes.
- **rt** route-target extended community.

Example

This command configures a well-known extended community for import and export of routes.

```
switch(config)# router bgp 100  
switch(config-router-bgp)# vni-aware-bundle bundle1  
switch(config-macvrf-bundle1)# route-target both 503:12  
switch(config-macvrf-bundle1)#{
```

18.18.11 route-target export

The **route-target export** command allows you to export routes from a VRF to the local VPN table using the route target extended community list.

The **no route-target export** and **default route-target export** commands remove the routes from the VPN table.

Command Mode

Router-BGP VNI Configuration

Syntax

```
route-target export [evpn | vpn-ipv4 | vpn-ipv6] RT
no route-target export
default route-target export
```

Parameters

- **evpn** EVPN address family.
- **vpn-ipv4** MPLS L3 VPN IPv4 unicast address family.
- **vpn-ipv6** MPLS L3 VPN IPv6 unicast address family.
- **RT** route-target extended community.

Examples

- These commands export routes from **vrf-red** to the VPN table.

```
switch(config)# service routing protocols model multi-agent
switch(config)# mpls ip
switch(config)# router bgp 65001
switch(config-router-bgp)# vrf vrf-red
switch(config-router-bgp-vrf-vrf-red)# rd 1:1
switch(config-router-bgp-vrf-vrf-red)# route-target export vpn-ipv4 10:10
switch(config-router-bgp-vrf-vrf-red)# route-target export vpn-ipv6 10:20
```

- These commands export routes from **vrf-red** to the EVPN table.

```
switch(config)# router bgp 65001
switch(config-router-bgp)# vrf vrf-red
switch(config-router-bgp-vrf-vrf-red)# rd 1:1
switch(config-router-bgp-vrf-vrf-red)# route-target export evpn 10:1
```

18.18.12 route-target import

The **route-target import** command allows you to import route-target extended community lists from the local VPN table to the target VRF.

The **no route-target import** and **default route-target import** commands remove the routes from the VPN table.

Command Mode

Router-BGP VNI Configuration

Command Syntax

```
route-target import [evpn | vpn-ipv4 | vpn-ipv6] RT  
no route-target import  
default route-target import
```

Parameters

- **evpn** EVPN address family.
- **vpn-ipv4** MPLS L3 VPN IPv4 unicast address family.
- **vpn-ipv6** MPLS L3 VPN IPv6 unicast address family.
- **RT** route-target extended community.

Examples

- These commands import routes from the VPN table to **vrf-blue**.

```
switch(config)# service routing protocols model multi-agent  
switch(config)# mpls ip  
switch(config)# router bgp 65001  
switch(config-router-bgp)# vrf vrf-blue  
switch(config-router-bgp-vrf-vrf-blue)# rd 2:2  
switch(config-router-bgp-vrf-vrf-blue)# route-target import vpn-ipv4 10:10  
switch(config-router-bgp-vrf-vrf-blue)# route-target import vpn-ipv6 10:20
```

- These commands import routes from the EVPN table to **vrf-blue**.

```
switch(config)# router bgp 65001  
switch(config-router-bgp)# vrf vrf-blue  
switch(config-router-bgp-vrf-vrf-blue)# rd 2:2  
switch(config-router-bgp-vrf-vrf-blue)# route-target import evpn 10:1
```

18.18.13 route-target route-map

The **route-target route-map** command allows you to export and import route target extended community lists from one VRF to another using route maps.

The **no route-target route-map** and **default route-target route-map** commands remove the routes from the VPN table.

Command Mode

Router-BGP VNI Configuration

Command Syntax

```
route-target [import | export][evpn | vpn-ipv4 | vpn-ipv6] route-map RM
no route-target route-map
default route-target route-map
```

Parameters

- **evpn** EVPN address family.
- **vpn-ipv4** MPLS L3 VPN IPv4 unicast address family.
- **vpn-ipv6** MPLS L3 VPN IPv6 unicast address family.
- **RM** route-map extended community.

Examples

- These commands export routes from **vrf-red** to the VPN table.

```
switch(config)# service routing protocols model multi-agent
switch(config)# mpls ip
switch(config)# router bgp 65001
switch(config-router-bgp)# vrf vrf-red
switch(config-router-bgp-vrf-vrf-red)# rd 1:1
switch(config-router-bgp-vrf-vrf-red)# route-target export vpn-ipv4 10:10
switch(config-router-bgp-vrf-vrf-red)# route-target export vpn-ipv6 10:20
switch(config-router-bgp-vrf-vrf-red)# route-target export vpn-ipv4 route-map EXPORT_V4_ROU
TES_TO_VPN_TABLE
switch(config-router-bgp-vrf-vrf-red)# route-target export vpn-ipv6 route-map EXPORT_V6_ROU
TES_TO_VPN_TABLE
```

- These commands export routes from **vrf-red** to the EVPN table.

```
switch(config)# router bgp 65001
switch(config-router-bgp)# vrf vrf-red
switch(config-router-bgp-vrf-vrf-red)# rd 1:1
switch(config-router-bgp-vrf-vrf-red)# route-target export evpn 10:1
switch(config-router-bgp-vrf-vrf-red)# route-target export evpn route-map EXPORT_ROUTES
_TO_EVPN_TABLE
```

- These commands import routes from the VPN table to **vrf-blue**.

```
switch(config)# service routing protocols model multi-agent
switch(config)# mpls ip
switch(config)# router bgp 65001
switch(config-router-bgp)# vrf vrf-blue
switch(config-router-bgp-vrf-vrf-blue)# rd 1:1
switch(config-router-bgp-vrf-vrf-blue)# route-target import vpn-ipv4 10:10
switch(config-router-bgp-vrf-vrf-blue)# route-target import vpn-ipv6 10:20
switch(config-router-bgp-vrf-vrf-blue)# route-target import vpn-ipv4 route-map IMPORT_V4_ROU
TES_VPN_TABLE
switch(config-router-bgp-vrf-vrf-blue)# route-target import vpn-ipv6 route-map IMPORT_V6_ROU
TES_VPN_TABLE
```

-
- These commands import routes from the EVPN table to **vrf-blue**.

```
switch(config)# router bgp 65001
switch(config-router-bgp)# vrf vrf-blue
switch(config-router-bgp-vrf-vrf-blue)# rd 2:2
switch(config-router-bgp-vrf-vrf-blue)# route-target import evpn 10:1
switch(config-router-bgp-vrf-vrf-blue)# route-target import evpn route-map IMPORT_ROUTES
    _FROM_EVPN_TABLE
```

18.18.14 router general

The **router general** command places the switch in Router-General Configuration Mode for the configuration of protocol-independent routing.

The **no router general** and **default router general** commands remove all protocol-independent routing configuration from *running-config*.

Command Mode

Global Configuration

Command Syntax

```
router general  
no router general  
default router general
```

Example

- These commands place the switch in Router-General Configuration Mode and display the commands available there.

```
switch(config)# router general  
switch(config-router-general)# ?  
  command          Configuration command  
  control-functions Routing control functions configuration  
  hardware         Configure hardware-specific parameters  
  next-hops        Next hop configuration  
  rib              Routing table  
  route            Route commands  
  route-map        Route-map source configuration  
  router-id        Configure a general router ID for all routing processes  
  segment-routing   Segment Routing configuration  
  software          Software configuration  
  vrf               Enter VRF sub-mode  
  
switch(config-router-general) #
```

18.18.15 router multicast vrf leak

The **router multicast** command places the switch in router multicast configuration mode to configure virtual routing and forwarding multicast traffic.

Command Mode

Global Configuration

Command Syntax

```
router multicast vrf vrf-receiver-epvn leak group [prefix-list prefix-list-name][vrf vrf-name]
```

Parameters

- ***vrf-receiver-epvn*** - The name of the VRF receiver
- **group** - Traffic groups to leak
- ***prefix-list prefix-list-name*** - The name of the traffic group
- ***vrf vrf-name*** - The source of the multicast traffic

Example

The following command places the switch in **router multicast** configuration mode.

```
switch(config)# router multicast
switch(config-router-multicast)# vrf vrf-receiver-evpn1 leak
switch(config-router-multicast-vrf-vrf-receiver-evpn1)#leak group prefix-list prefix-list-name1
vrf traffic-source-vrf-name1
```

18.18.16 show bgp evpn

The `show bgp evpn` command displays information about the BGP-EVPN routes of the switch.

Command Mode

Global Configuration

Command Syntax

```
show bgp evpn [community | detail | esi esid | extcommunity | host-flap | instance | large-community AS:nn:nn | next-hop | rt | admin:local-assignment | route-type | summary | vni vni_num]
```

Parameters

- ***no parameters*** displays all routes of the switch.
- **community** displays routes filtered by the specified community. Options include:
 - **GSHUT** well known GSHUT community.
 - **aa:nn** AS and network number, separated by colon. The value ranges from **1** to **4294967295**.
 - **internet** advertises route to the Internet community.
 - **local-as** advertises route only to local peers.
 - **no-advertise** does not advertise the route to any peer.
 - **no-export** advertises route only within the BGP-EVPN AS boundary.
 - **comm_num** community number. Values range from **1** to **4294967040**.
- **detail** displays detailed information of routes.
- **esi esid** displays routes filtered by the specified Ethernet Segment Identifier (ESI).
- **extcommunity** displays routes that match with BGP or VPN extended community list. Options include:
 - **esi-label esid** displays routes filtered by the specified value of ESI label. The value ranges from **0** to **16777215**.
 - **mac-mobility** displays routes filtered by the specified MAC mobility.
 - **rt** displays routes filtered by the specified route target.
 - **tunnel-encap VXLAN** displays routes filtered by the VXLAN tunnel encapsulation.
 - **router-mac H.H.H** displays routes filtered by the specified router MAC address.
- **host-flap** displays routes that contains MAC addresses that are blacklisted due to duplication.
- **instance** displays routes with EVPN instances.
- **large-community AS:nn:nn** displays routes filtered by the specified large community.
- **next-hop** displays routes filtered by next-hop IPv4 or IPv6 addresses of remote VTEP.
- **rd admin:local-assignment** displays routes filtered by the specified Route Distinguisher (RD).
- **route-type** displays routes filtered by NLRI route type.
- **summary** displays a summary of routes.
- **vni vni_num** displays routes filtered by the specified VXLAN Network Identifier (VNI). Value ranges from **1** to **4294967294**.

Examples

- This command displays BGP-EVPN routes filtered by the **VNI 3011**.

```
switch(config-router-bgp-af) # show bgp evpn vni 3011
BGP routing table information for VRF default
Router identifier 2.0.2.2, local AS number 65002
Route status codes: s - suppressed, * - valid, > - active, # - not installed, E - ECMP head, e
- ECMP
      S - Stale, c - Contributing to ECMP, b - backup
      % - Pending BGP convergence
```

```

Origin codes: i - IGP, e - EGP, ? - incomplete
AS Path Attributes: Or-ID - Originator ID, C-LST - Cluster List, LL Nexthop - Link Local
Nexthop

```

18.18.17 show e-tree vlan

The **show e-tree vlan** command displays configuration information about E-Tree on VLANs.

Command Mode

EXEC

Command Syntax

```
show e-tree vlan
```

Example

To display information about E-Tree on VLANs, use the following command:

```
switch# show e-tree vlan
VLAN      E-Tree Role      Remote Leaf Install Mode
-----
100       Leaf             Install drop route
200       Leaf             Do not install
```

18.18.18 show ip bgp vrf

The **show ip bgp vrf** command displays the type of VPN from the imported route. It indicates that the IPv4 route has been leaked and displays source VRF information.

Command Mode

Global Configuration

Command Syntax

```
show ip bgp vrf [vrf_name | all | default]
```

Parameters

- **vrf_name** name of the VRF.
- **all** displays summary of all VRFs.
- **default** default virtual routing and forwarding instance.

Example

This command displays the leaked and source VRF information.

```
switch(config)# show ip bgp 13.0.0.0/24 vrf vrf-blue
BGP routing table information for VRF vrf-blue
Router identifier 5.0.0.2, local AS number 65001
BGP routing table entry for 130.110.61.0/24
    4.0.0.3 from 4.0.0.3 (52.0.0.1), imported EVPN route, RD 400:1
        Origin IGP, metric -, localpref 100, weight 0, valid, external,best
        Extended Community: Route-Target-AS:4000:1 TunnelEncap:tunnelTypeVXLAN
    EvpnRouterMac:74:83:ef:0b:70:f3
        Leaked from VRF vrf-red
```

18.18.19 show ip route vrf

The **show ip route vrf** command displays leaked prefixes with the label **L** in the output that indicates that the IPv4 route has been leaked. It also displays information about the source VRF from which these prefixes have been leaked.

Command Mode

Global Configuration

Command Syntax

```
show ip route vrf [vrf_name | all]
```

Parameters

- vrf_name** name of the VRF.
- all** displays summary of all VRFs.

Example

These commands display the OSPF or OSPFv3 leaked routes as **redistribute ospf** and **redistribute ospfv3** are configured on the source VRF **vrf-red**.

```
switch(config)# show ip route vrf vrf-blue
VRF: vrf-blue
Codes: C - connected, S - static, K - kernel,
       O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
       E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
       N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP,
       R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
       O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
       NG - Nexthop Group Static Route, V - VXLAN Control Service,
       DH - DHCP client installed default route, M - Martian,
       DP - Dynamic Policy Route, L - VRF Leaked
Gateway of last resort is not set
C      5.0.0.2/31 is directly connected, Ethernet14
B L  57.0.0.3/32 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
B L  45.0.0.1/32 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
B L  52.0.0.1/32 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
B L  120.0.0.0/24 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
B L  130.0.0.0/24 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
B L  130.0.1.0/24 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
B L  130.0.2.0/24 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
B L  130.0.3.0/24 [200/0] (source VRF vrf-red) via 4.0.0.3, Ethernet11
```

18.18.20 show ipv6 bgp vrf

The **show ipv6 bgp vrf** command displays the type of VPN from the imported route. It shows an indication that the IPv6 route has been leaked and source VRF information is displayed.

Command Mode

Global Configuration

Command Syntax

```
show ipv6 bgp vrf [vrf_name | all | default]
```

Parameters

- **vrf_name** name of the VRF.
- **all** displays a summary of all VRFs.
- **default** default virtual routing and forwarding instance.

Example

This command displays the leaked and source VRF information.

```
switch(config)# show ipv6 bgp 2001:10:1:0::102/64 vrf default
BGP routing table information for VRF default
Router identifier 218.218.218.218, local AS number 34
Route status codes: s - suppressed, * - valid, > - active, # - not installed, E
- ECMP head, e - ECMP
      S - Stale, c - Contributing to ECMP, b - backup, L -
labeled-unicast
      % - Pending BGP convergence
Origin codes: i - IGP, e - EGP, ? - incomplete
AS Path Attributes: Or-ID - Originator ID, C-LST - Cluster List, LL Nexthop -
Link Local Nexthop

      Network          Next Hop           Metric  LocPref Weight  Path
* >   2000:0:14:120::/64  2001:db8:1111:9000::  -    100    109    i
*     2000:0:14:120::/64  2001:db8:156:1010::2  -    100    0      i
*     2000:0:14:120::/64  2001:db8:152:1010::2  -    100    0      i
*     2000:0:14:120::/64  2001:db8:203:1010::2  -    100    0      i
```

18.18.21 show ipv6 route vrf

The **show ipv6 route vrf** command displays leaked prefixes with the label **L** in the output that indicates that the IPv6 route has been leaked. It also displays information about the source VRF from which these prefixes have been leaked.

Command Mode

Global Configuration

Command Syntax

```
show ipv6 route vrf [vrf_name | all]
```

Parameters

- vrf_name** the name of the VRF.
- all** displays a summary of all VRFs.

Example

These commands display the OSPF or OSPFv3 leaked routes as **redistribute ospf** and **redistribute ospfv3** are configured on the source VRF **vrf-red**.

```
switch(config)# show ipv6 route vrf vrf-blue
VRF: vrf-blue
Displaying 802 of 802 IPv6 routing table entries
Codes: C - connected, S - static, K - kernel, O3 - OSPFv3, B - BGP, R - RIP, A B - BGP Aggregate,
I L1 - IS-IS level 1, I L2 - IS-IS level 2, DH - DHCP, NG - Nexthop Group Static Route, M -
Martian,
DP - Dynamic Policy Route, L - VRF Leaked
      B L  18::1/128 [200/0] (source VRF vrf-red)
          via 4::3, Ethernet11
      B L  6::2/127 [200/0] (source VRF vrf-red)
          via fe80::7683:efff:fe0b:963d, Ethernet11
      B L  45::1/128 [200/0] (source VRF vrf-red)
          via fe80::7683:efff:fe0b:963d, Ethernet11
      B L  130::/64 [200/0] (source VRF vrf-red)
          via fe80::7683:efff:fe0b:963d, Ethernet11
      B L  130:0:0:1::/64 [200/0] (source VRF vrf-red)
          via fe80::7683:efff:fe0b:963d, Ethernet11
      B L  130:0:0:2::/64 [200/0] (source VRF vrf-red)
          via fe80::7683:efff:fe0b:963d, Ethernet11
      B L  130:0:0:3::/64 [200/0] (source VRF vrf-red)
```

18.18.22 show l2rib input all

Use the `show l2rib input all` command to display the Layer 2 RIB input tables migration process.

Command Mode

EXEC

Command Syntax

```
show l2rib input all [ detail | floodset [ vlan | vtep ] | interface [ Ethernet | Port-Channel ] | mac H.H.H |  
vlan vlan_id | vtep [ A.B.C.D | A:B:C:D:E:F:G:H ]
```

Parameters

- **detail** Displays a more comprehensive output.
- **floodset** Displays L2Rib floodset from input source.
 - **vlan** Filter by VLAN ID.
 - **vtep** Filter by VTEP.
- **interface** Filter by destination interface.
 - **Ethernet** Ethernet interface.
 - **Port-Channel** Link Aggregation Group (LAG).
- **mac *H.H.H*** Filter by MAC address.
- **vlan *vlan_id*** Filter by VLAN ID.
- **vtep** Filter by VTEP.
 - **A.B.C.D** IP address of VTEP.
 - **A:B:C:D:E:F:G:H** IP address of VTEP.

18.18.23 show l2Rib input VXLAN-control-service

Use the **show l2Rib input VXLAN-control-service** to display the migration processes for the VXLAN control service.

Command Mode

EXEC

Command Syntax

```
show l2Rib input VXLAN-control-service [detail | floodset [vlan | vtep] interface [ Ethernet | Port-Channel]] mac H.H.H | vlan vlan_id | vtep [A.B.C.D | A:B:C:D:E:F:G:H]
```

Parameters

- **detail** Displays a more comprehensive output.
- **floodset** Displays L2Rib floodset from input source.
 - **vlan** Filter by VLAN ID.
 - **vtep** Filter by VTEP.
- **interface** Filter by destination interface.
 - **Ethernet** Ethernet interface.
 - **Port-Channel** Link Aggregation Group (LAG).
- **mac** Filter by MAC address.
 - **H.H.H** Ethernet address.
- **vlan *vlan_id*** Filter by VLAN ID.
- **vtep** Filter by VTEP.
 - **A.B.C.D** IP address of VTEP.
 - **A:B:C:D:E:F:G:H** IP address of VTEP.

18.18.24 show l2rib output

Use the **show l2rib output** command to display the the Layer 2 RIB utput tables migration process.

Command Mode

EXEC

Command Syntax

```
show l2rib output [detail | floodset [vlan | vtep] | mac H.H.H | vlan vlan_id | vtep [A.B.C.D |  
A:B:C:D:E:F:G]
```

Parameters

- **detail** Displays a more comprehensive output.
- **floodset** Displays L2Rib floodset from input source.
 - **vlan** Filter by VLAN ID.
 - **vtep** Filter by VTEP.
- **interface** Filter by destination interface.
 - **Ethernet** Ethernet interface.
 - **Port-Channel** Link Aggregation Group (LAG).
- **mac H.H.H** Filter by MAC address.
- **vlan *vlan_id*** Filter by VLAN ID.
- **vtep** Filter by VTEP.
 - **A.B.C.D** IP address of VTEP.
 - **A:B:C:D:E:F:G:H** IP address of VTEP.

18.18.25 show service VXLAN address-table

The **show service VXLAN address-table** command displays route entries in the MAC forwarding table that are added through the CVX.

Command Mode

CVX Global Configuration

Command Syntax

```
show service VXLAN address-table {advertised | received}[address H.H.H | evpn | hsc | mss | switch [Word | all] | vni vnid | vtep A.B.C.D]
```

Parameters

- advertised** displays the advertised route entries in the MAC forwarding table.
- received** displays the received route entries in the MAC forwarding table.
- address H.H.H** displays route entries that are filtered by the specified MAC addresses.
- evpn** displays route entries filtered by BGP-EVPN.
- hsc** displays route entries filtered by Hardware Switch Controller (HSC).
- mss** displays route entries filtered by Macro Segmentation Service (MSS).
- switch** displays route entries that are filtered by the specified switch or all switches. Options include:
 - Word** Hostname, IP address or ID of the switch.
 - all** all switches.
- vni vnid** displays route entries filtered by the specified VXLAN Network Identifier (VNI). Value ranges from 1 to **4294967294**.
- vtep A.B.C.D** displays route entries filtered by the specified IP address of the remote Virtual Tunnel End Point (VTEP).

Examples

- This command displays the route entries in MAC forwarding table advertised to BGP-EVPN peers.

```
cvx# show service VXLAN address-table advertised evpn

      Advertised Mac Address Table
-----
VNI      Mac Address      VTEP      Moves
-----
1000    02:01:62:01:00:00 10.0.0.1      1
Total Mac Addresses for this criterion: 1

      Advertised Flood Table
-----
VNI      Mac Address      VTEP(s)
-----
1000    00:00:00:00:00:00 10.0.0.1 10.0.0.2
Total Mac Addresses for this criterion: 1 cvx#
```

- This command displays the route entries in MAC forwarding table received from BGP-EVPN peers.

```
switch# show service VXLAN address-table received evpn

      Received Mac Address Table
-----
Source   VNI      Mac Address      VTEP      Moves
-----
EVPN     1000    02:01:62:02:00:00 10.0.0.3      1
Total Mac Addresses for this criterion: 1

      Received Flood Table
-----
```

| Source | VNI | Mac Address | VTEP |
|---|------|-------------------|----------|
| <hr/> | | | |
| EVPN | 1000 | 00:00:00:00:00:00 | 10.0.0.3 |
| EVPN | 1000 | 00:00:00:00:00:00 | 10.0.0.4 |
| Total Mac Addresses for this criterion: 2 switch# | | | |

18.18.26 show vrf leak flapping

The **show vrf leak flapping** command displays the flapping prefixes of the routes leaked from one VRF to another VRF. Routes that are detected as “flapping” are blocked considering the future leaking policy execution.

Command Mode

EXEC

Command Syntax

```
show vrf leak flapping
```

Parameters

- **destination** displays flapping prefixes destined to a VRF.
- **prefix** displays flapping routes for a prefix.
- **source** displays flapping prefixes sourced from a VRF.
- **vrf** displays flapping prefixes associated with a VRF.

Example

This command displays the flapping prefixes of the leaked routes.

```
switch# show vrf leak flapping
```

| Age | Source VRF | Destination VRF | Prefix | Created At |
|-----|------------|-----------------|-------------|---------------|
| 141 | VRF1 | VRF2 | 10.0.2.0/24 | 3357281.40992 |

18.18.27 show VXLAN control-plane

To enable the user to quickly view which control planes and sources are importing reachability information into which VLANs, use the following show command:

Command Mode

EXEC

Command Syntax

```
show VXLAN control-plane [ export vlan [ $ | vlan_id ] | import vlan [ $ | vlan_id ] ][vlan [ $ | vlan_id ]]
```

Parameters

- **export** Restricts output to VLANs exporting to a control plane.
 - **vlan** Specifies specific VLANs to display control plane information.
 - **\$** List end.
 - ***vlan_id*** VLAN ID. Range **1-4094**.
- **import** Restricts output to VLANs importing from a control plane.
 - **\$** List end.
 - ***vlan_id*** VLAN ID. Range **1-4094**.
- **vlan** Specifies specific VLANs to display control plane information.
 - **\$** List end.
 - ***vlan_id*** VLAN ID. Range **1-4094**.

18.18.28 vlan (VLAN-AWARE-Bundle configuration mode)

The **vlan add/ remove** command configures the VLAN range string in a VLAN-AWARE-BUNDLE. When the add and remove options are not used, the currently configured range is replaced by the new one. The add and remove options update the currently configured range-aware bundles by adding or removing the provided VLAN range from the currently configured range respectively.

Command Mode

VLAN-AWARE-BUNDLE Configuration

Command Syntax

```
vlan [add | remove] range
```

Parameter

range is the range specified.

Example

These commands take an existing vlan-aware-bundle configuration, **corporate_100**, and modify it with the add and remove options.

```
(Existing configuration for corporate_100)
vlan-aware-bundle corporate_100
  rd 1.1.1.1:100
  route-target both 100:100
  vlan 1-10

switch(config-vlan-aware-bundle)#vlan add 1000

(Modified configuration for corporate_100)
vlan-aware-bundle corporate_100
  rd 1.1.1.1:100
  route-target both 100:100
  vlan 1-10, 1000

switch(config-vlan-aware-bundle)#vlan remove 5

(Updated configuration for corporate_100)
vlan-aware-bundle corporate_100
  rd 1.1.1.1:100
  route-target both 100:100
  vlan 1-4, 6-10, 1000
```

18.18.29 vni-aware-bundle

The **vni-aware-bundle** command configures a BGP MAC-VRF containing Layer 2 routes from a group of VXLAN Network Identifiers (VNI).

Command Mode

Router BGP Configuration

Command Syntax

```
vni-aware-bundle vni_bundle_name
```

Parameter

vni_bundle_name VNI bundle name.

Example

This command configures MAC-VRF BGP to support VNI bundle1.

```
cvx(config)# router bgp 100
cvx(config-router-bgp)# vni-aware-bundle bundle1
cvx(config-macvrf-bundle1)#

```

Multiprotocol Label Switching (MPLS)

Tunneling protocols encapsulate packets of a different protocol as the payload of a larger frame for delivery within networks utilizing the encapsulating protocol. Tunneling facilitates the delivery of payload over an incompatible delivery network and creates a secure path through an untrusted network. Protocols that this chapter describes include MPLS, Decap Groups, and Nexthop Groups.

Sections in this chapter include:

- [MPLS](#)
- [BGP/MPLS L3 VPN](#)
- [EVPN MPLS Shared ESI Label](#)
- [LDP Pseudowire](#)
- [LDP Entropy Label](#)
- [MPLS Commands](#)

19.1 MPLS

These sections describe the Arista MPLS implementation:

- [Configuring MPLS](#)

19.1.1 MPLS Overview

Multiprotocol Label Switching (MPLS) provides a networking process that replaces complete network addresses with short path labels for directing data packets to network nodes. The labels identify virtual links (paths) between distant nodes rather than endpoints. MPLS is scalable and protocol-independent. MPLS assigns labels to data packets and uses the labels to determine packet forwarding destinations without examining the packet.

Arista switches utilize MPLS to improve efficiency and control from servers through data centers and the WAN. The MPLS implementation supports manually configured static MPLS tunneling on each switch or established over a network by an SDN Controller. The configuration specifies a set of rules that filter packets based on matching criteria. Each rule applies MPLS-related actions to packets that match the rule criteria. Each rule includes a metric that the switch uses to select an action when multiple rules match a packet.

19.1.2 MPLS Implementation

MPLS static rule parameters contain the following information:

- A 20-bit value compared to the top header label of each MPLS packet. Other rule parameters may be applied to packets with matching top-label values.
- A next hop location that specifies the packet's next destination, IPv4 or IPv6, and the interface through which the switch forwards the packet.
- An MPLS label stack management action performed on filtered packets:
 - **pop-payload** - Removes the top label from the stack and terminates an Label-Switched Path (LSP).

- **swap-label** - Replaces the top label with a specified new label and passes a packet along an LSP.
- A rule metric to select a rule when multiple rules match an MPLS packet.

The switch drops packets that do not match any MPLS rules.

19.1.3 MPLSoGRE Filtered Mirroring

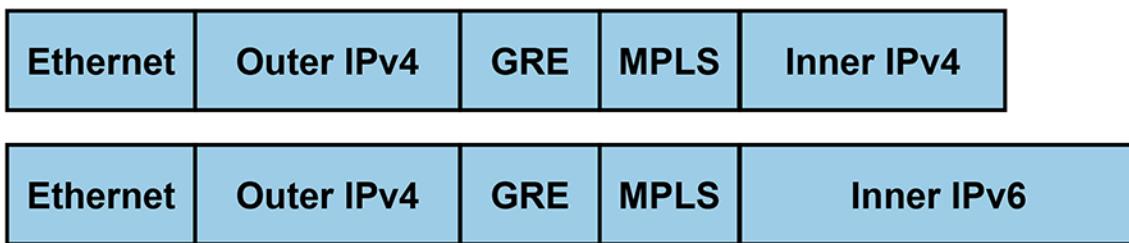

In MPLS over Generic Routing Encapsulation (MPLSoGRE) filtered mirroring, IPv4 over MPLS over GRE and IPv6 over MPLS over GRE packets that enter a GRE tunnel endpoint where MPLS performs a lookup, and selects packets for mirroring based on the destination IP address field in the inner IPv4 or IPv6 header.

Note: MPLS does not select packets for mirroring if forwarded based on either the L2 or outer L3 header destination address.

The header has the following format for the packets selected for mirroring:

Figure 19-1: Header Format of Packets

When mirroring to a GRE tunnel, the payload of the outgoing GRE packet contains the payload of the incoming source packet starting from the MPLS header. EOS strips L2 and outer L3 headers from the mirror copy. When the MPLS lookup fails, the packet becomes eligible for mirroring based on the selection criteria defined in the ACL.

19.1.4 Mixed TTL/DSCP in MPLS Tunnel Termination

A Label Edge Router (LER) decapsulating an MPLS packet may choose to source the TTL and DSCP fields from either the MPLS header or the original inner IPv4 header. However, some applications need the TTL field value from the MPLS header, while retaining the DSCP from the original IPv4 header. Mixed TTL/DSCP in MPLS Tunnel Termination enables tunnel termination to select this specific mix of two modes.

This section contains the following topics:

- [Configuring Mixed TTL/DSCP in MPLS Tunnel Termination](#)
- [Packet Support for IPv6](#)

19.1.4.1 Configuring Mixed TTL/DSCP in MPLS Tunnel Termination

Configure mixed TTL/DSCP in MPLS tunnel termination with MPLS VRF decapsulation. Therefore, the switch requires a static VRF-to-MPLS-label map:

```
switch(config)# mpls ip
switch(config)# mpls static vrf-label mpls-label vrf vrf-name
switch(config)# ip routing vrf vrf-name
```

Use the **TTL uniform** and **DSCP pipe** options with the **mpls tunnel termination** command:

```
switch(config)# mpls tunnel termination model ttl uniform dscp pipe
```

Configure the TCAM profile:

```
switch(config)# hardware tcam
# May use any profile that provides "qos ip"
switch(config-tcam)# profile name copy default
switch(config-tcam-profile-name)# feature qos ip
switch(config-tcam-profile-name-feature-qos-ip)# packet mpls ipv4 forwarding routed decap
switch(config-tcam)# system profile name
```

19.1.4.1.1 Packet Support for IPv6

RFE 391109 brings mixed TTL/DSCP support for IPv6 over MPLS packets as well. The TCAM profile configuration is similar to the above IPv4 configuration:

```
switch(config)# hardware tcam
# May use any profile that provides "qos ipv6"
switch(config-tcam)# profile name copy default
switch(config-tcam-profile-name)# feature qos ipv6
switch(config-tcam-profile-name-ipv6)# packet mpls ipv6 forwarding routed decap
switch(config-tcam)# system profile name
```

19.1.5 Support for MPLS Packets in IP ACLs

Ingress and egress IPv4 and IPv6 access-lists do not automatically match the inner IP header when processing IP over MPLS traffic.

EOS supports matching of the inner IP header in an access-list by adding the proper packet types to the corresponding TCAM features.

19.1.6 DSCP-to-TC Maps for MPLS Traffic to Layer 3 VRFs

MPLS-labeled traffic, both IPv4 and IPv6, can be decapsulated and routed using a specific VRF, either the default or a named VRF. The MPLS label can be statically assigned to a specific VRF, or dynamically through L3 EVPN MPLS. In this configuration, the switch adds a traffic class label based on a packet's ingress DSCP to the decapsulated MPLS packet if directed to a specific VRF. This provides an MPLS tunneling technique called **Short Pipe Mode**.

A QoS map steers the mapping of DSCP labels to a traffic class. Up to 10 custom maps can be applied. A map only uses hardware resources when attached to at least one VRF. When first creating a map, the DSCP-to-TC map copies the configuration from the global map, and subsequent changes to the global map do not have any effect on custom maps.

19.1.7 Configuring MPLS

Enable MPLS routing using the **mpls ip** command.

Use the following command to enable MPLS routing.

```
switch(config)# mpls ip
switch(config)# show running-config mpls ip
!
```

```
end  
switch(config) #
```

The **mpls static** command creates MPLS rules. MPLS static rules identify a set of MPLS packets by a common top label and defines the method of handling these packets.

Use the following commands to create an MPLS rule that matches packets with a top label value of **3400** and causes the removal of the top label from the header stack. Configure the next hop destination of the IPv4 payload as the IPv4 address **10.14.4.4** using the **interface ethernet 3/3/3**. This rule has a metric value of **100**.

```
switch(config) # mpls static top-label 3400 ethernet 3/3/3 10.14.4.4 pop payload-type  
    ipv4  
switch(config) # show running-config  
  
!  
mpls static top-label 3400 Ethernet3/3/3 10.14.4.4 pop payload-type ipv4  
!  
  
end  
switch(config) #
```

These commands create a backup rule that forwards the packet through **interface ethernet 4/3**. This rule's metric value of **150** assigns it backup status prior to the first rule.

```
switch(config) # mpls static top-label 3400 ethernet 4/3 10.14.4.4 pop payload-type ipv4  
    metric 150  
switch(config) # show running-config  
  
!  
mpls static top-label 3400 Ethernet4/3 10.14.4.4 pop payload-type ipv4 metric 150  
mpls static top-label 3400 Ethernet3/3/3 10.14.4.4 pop payload-type ipv4  
!  
  
end  
switch(config) #
```

Create an MPLS rule that forwards the packet to the nexthop address through any interface:

```
switch(config) # mpls static top-label 4400 10.15.46.45 pop payload-type ipv4  
switch(config) # show running-config  
  
!  
mpls static top-label 3400 Ethernet4/3 10.14.4.4 pop payload-type ipv4 metric 150  
mpls static top-label 3400 Ethernet3/3/3 10.14.4.4 pop payload-type ipv4  
mpls static top-label 4400 10.15.46.45 pop payload-type ipv4  
!  
  
end  
switch(config) #
```

Configure a static tunnel for the tunnel endpoint **64.0.0.1** and add a label **11111** to it.

```
switch(config) # mpls static STATIC 64.0.0.1/32 54.0.0.1 Port-Channel17 label-stack 11111
```

The following example shows an MPLS swap route configuration. The following command swaps a packet with MPLS top label **3400** to **5600** for forwarding to **10.14.4.4**.

```
switch(config)# mpls static top-label 3400 10.14.4.4 swap 5600
switch(config)#

```

The following example shows MPLS next-hop groups configuration for MPLS. The following commands configures the specification of a next hop group called **TestGrp1** with two entries.

```
switch(config)# nexthop-group TestGrp1 type MPLS
switch(config-nexthop-group=TestGrp1)# size 2
switch(config-nexthop-group=TestGrp1)# entry 0 push label-stack 70 nexthop 10.20.30.5
switch(config-nexthop-group=TestGrp1)# entry 1 push label-stack 71 nexthop 10.20.30.6
switch(config-nexthop-group=TestGrp1)# exit
switch(config)#

```

The **label-stack** parameter accepts only one label. **Tunnel-source** and **ttl** commands do not apply to MPLS NexthopGroups. The nexthop entry resolves when the entry specifies a remote next hop. The **show** command indicates the resolved, directly-attached nexthop.

Display the switch's MPLS static rule configuration for specified routes and rules using the [show mpls route](#).

```
switch# show mpls config route
In-Label Out-Label Metric Payload NextHop
3400 pop 100 ipv4 10.14.4.4,Et3/3/3
3400 pop 150 ipv4 10.14.4.4,Et4/3 switch#

```

Display statistics about the configuration and implementation of MPLS rules using the [show mpls route summary](#) command.

```
switch# show mpls route summary
Number of Labels: 1 (1 unprogrammed)
Number of adjacencies in hardware: 0
Number of backup adjacencies: 2 switch#

```

The **show mpls lfib route** command displays the Label Forward Information Base of the switch.

```
switch(config)# show mpls lfib route
MPLS forwarding table (Label [metric] Vias) - 1 routes

19.1.7.2 Configuring Egress IPv4 and IPv6 over MPLS ACLs

By default, IPv4 and IPv6 over MPLS packets use ACLs at the egress stage by default, applicable only to IPv4 and IPv6 over MPLS packets with a popped MPLS label. Override this behavior if required by disabling egress ACLs for certain MPLS labels. The switch does not require a special configuration to enable egress ACLs on IPv4 and IPv6 over MPLS packets.

Examples

- This command disables egress ACLs for MPLS top-label **12000** on the egress interface **120.1.1.1** next hop address.

```

switch(config)# no mpls static top-label 12000 120.1.1.1 pop payload-type ipv6
switch(config)#

```

- This command enables egress ACLs for MPLS top-label **12000** on the egress interface **120.1.1.1** next hop address.

```

switch(config)# mpls static top-label 12000 120.1.1.1 pop payload-type ipv6
switch(config)#

```

19.1.7.3 Configuring MPLSoGRE Filtered Mirroring

Configure the filtered mirroring of terminated MPLSoGRE packets by creating an IPv4 access list, and then attaching the IPv4 access list to a monitor session source with a tunnel decap group. This IPv4 access-list has rules that match to either inner IPv4 or IPv6 destination addresses.

Enabling the TC-Counters TCAM Profile

The following limitations apply to MPLSoGRE filtered mirroring in tc-counters TCAM profile:

- EOS does not enforce security ACLs on IPv4oMPLSoGRE and IPv6oMPLSoGRE terminated packets.
- Set the rules of a mirroring-ACL to match either inner IPv4 or inner IPv6 header fields, but not both.

The ACLs containing rules to match both inner IPv4 and inner IPv6 header fields do not apply to a single source interface in multiple mirroring sessions. In other words, all ACLs applied to a shared source interface must contain either inner IPv4 rules or inner IPv6 rules.

The following commands switch to the tc-counters TCAM profile in the running configuration.

```
switch(config) # hardware tcam
switch(config-hw-tcam) # system profile tc-counters
switch(config-hw-tcam) # exit
```

Defining Two IPv4 Access-Lists

The [ip access-list](#) command places the switch in ACL configuration mode, a group change mode that modifies an IPv4 access control list. The command specifies the name of the IPv4 ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All changes in a group change mode edit session are pending till the end of the session.

The [permit \(Role\)](#) command configures one access-list to match the inner IPv4 address, and the other access-list to match the inner IPv6 address.

```
switch(config) # ip access-list dIPv4
switch(config) # 10 permit ip any any inner ip any host 5.5.5.5
switch(config) # exit

switch(config) # ip access-list dIPv6
switch(config) # 10 permit ip any any inner ipv6 any host 55::55
switch(config) # exit
```

Attaching Access-Lists

The [monitor session source](#) and [monitor session destination](#) commands allow to attach two access lists to two different monitor session sources.

```
switch(config) # monitor session sess1 source et1 rx ip access-group dIPv4
switch(config) # monitor session sess1 destination tunnel mode gre source 1.1.1.1 destination
               2.2.2.2
switch(config) # monitor session sess2 source et2 rx ip access-group dIPv6
switch(config) # monitor session sess2 destination tunnel mode gre source 3.3.3.3 destination
               4.4.4.4
switch(config) # show monitor session

Session sess1

switch(config)#

```

19.1.7.4 Configuring Support IP ACLs for MPLS Packets

19.1.7.4.1 Configuring Ingress IP Access Control (ACL) List Support

To facilitate inner IP header matching, EOS supports two TCAM profile packet types:

```

packet mpls ipv4 forwarding bridged
packet mpls ipv4 forwarding mpls

```

The ingress inner IP header matching creates a user-defined profile with these new packet types. Although MAC access-lists do not match on the inner IP header, you must add this packet type in order to generate a lookup for MPLS packets if using MAC ACLs.

```

switch(config) # hardware tcam
switch(config-tcam) # profile MyMPLS copy default
switch(config-tcam-profile-MyMPLS) # feature acl port ip
switch(config-tcam-feature-acl-port-ip) # packet mpls ipv4 forwarding bridged
switch(config-tcam-feature-acl-port-ip) # packet mpls ipv4 forwarding mpls
switch(config-tcam-feature-acl-port-ip) # exit
switch(config-tcam-profile-MyMPLS) # feature acl port ipv6
switch(config-tcam-feature-acl-port-ipv6) # packet mpls ipv6 forwarding bridged
switch(config-tcam-feature-acl-port-ipv6) # packet mpls ipv6 forwarding mpls
switch(config-tcam-profile-MyMPLS) # feature acl port mac
switch(config-tcam-feature-acl-port-mac) # packet mpls ipv4 forwarding bridged
switch(config-tcam-feature-acl-port-mac) # packet mpls ipv4 forwarding mpls
switch(config-tcam-feature-acl-port-mac) # packet mpls ipv6 forwarding bridged
switch(config-tcam-feature-acl-port-mac) # packet mpls ipv6 forwarding mpls

```

EOS supports ingress on inner IP header matching in MPLS packets on PBR ACLs. To enable this, the following must be configured in a user-defined TCAM profile:

```

switch(config-tcam) profile pbr-acls copy default
switch(config-tcam-profile-pbr-acls) # feature pbr mpls
switch(config-tcam-feature-pbr-mpls) # packet ipv4 forwarding mpls
switch(config-tcam-feature-pbr-mpls) # exit
switch(config-tcam-profile-pbr-acls) # feature pbr mpls
switch(config-tcam-feature-pbr-mpls) # packet mpls ipv6 forwarding mpls

```

19.1.7.4.2 Configuring Egress IPv4 and IPv6 over MPLS ACLs

By default, IPv4 and IPv6 over MPLS packets use ACLs at the egress stage by default, applicable only to IPv4 and IPv6 over MPLS packets with a popped MPLS label. Override this behavior if required by disabling egress ACLs for certain MPLS labels. The switch does not require a special configuration to enable egress ACLs on IPv4 and IPv6 over MPLS packets.

Examples

- This command disables egress ACLs for MPLS top-label **12000** on the egress interface **120.1.1.1** next hop address.

```

switch(config) # no mpls static top-label 12000 120.1.1.1 pop payload-type ipv6

```

```
switch(config) #
```

- This command enables egress ACLs for MPLS top-label **12000** on the egress interface **120.1.1.1** next hop address.

```
switch(config) # mpls static top-label 12000 120.1.1.1 pop payload-type ipv6
switch(config) #
```

19.1.7.4.3 Configuring MPLS Pop Terminated Packets

To enable the use of these qualifiers on MPLS-terminated packets by last label pop, this feature must be applied to the current TCAM profile, for example, *MyMPLS*:

```
switch(config) # hardware tcam
switch(config-tcam) # profile MyMPLS
switch(config-tcam-profile-MyMPLS) # feature acl port ip packet egress mpls-tunneled-match
switch(config-tcam-feature-acl-port-ip-egress-mpls-tunneled-match) #
```

By default, EOS does not enable this feature on all system profiles. Some TCAM profiles may also use the resources required by this feature. This requires verification to ensure the current user-defined TCAM profile supports this feature.

```
switch(config) # hardware tcam
switch(config-tcam) # profile egress-mpls copy MyMPLS
```

19.1.7.4.4 Configuring MPLS VRF-Decapsulated Packets

To enable the use of these new qualifiers on MPLS-terminated packets by last label VRF-label mapping, the packet type **mpls ipv4 forwarding routed decap** must be applied to at least one feature in the TCAM profile.

```
switch(config) # hardware tcam
switch(config-tcam) # profile VRF-Decap copy default
switch(config-tcam-profile-VRF-Decap) # feature qos ip packet mpls ipv4
forwarding routed decap
```

19.1.7.5 Supporting Traffic Policy on Interfaces

Access Control Lists (ACL) configures the action for packets traversing the packet processor pipeline based on different fields of packets. Usually, this requires the TCAM to match packets with multiple entries matching the list of IP addresses. The TCAM has limited resources, so traffic-policy performs transformation of the fields of the packet, and summarizes them in terms of the relevant rules this field matches by using command **interface traffic-policy**.

Custom TCAM Profile

The following commands enable a custom TCAM profile to support a traffic policy.

```
switch(config) # hardware tcam
switch(config-tcam) # profile traffic-policy
switch(config-tcam-profile-traffic-policy) # feature acl port mac
switch(config-tcam-feature-acl-port-mac) # sequence 55
switch(config-tcam-feature-acl-port-mac) # key size limit 160
switch(config-tcam-feature-acl-port-mac) # key field dst-mac ether-type src-mac
switch(config-tcam-feature-acl-port-mac) # action count drop
```

```

switch(config-tcam-feature-acl-port-mac)# packet ipv4 forwarding bridged
switch(config-tcam-feature-acl-port-mac)# packet ipv4 forwarding routed
switch(config-tcam-feature-acl-port-mac)# packet ipv4 forwarding routed multicast
switch(config-tcam-feature-acl-port-mac)# packet ipv4 mpls ipv4 forwarding mpls decap
switch(config-tcam-feature-acl-port-mac)# packet ipv4 mpls ipv6 forwarding mpls decap
switch(config-tcam-feature-acl-port-mac)# packet ipv4 non-VXLAN forwarding routed decap
switch(config-tcam-feature-acl-port-mac)# packet ipv4 VXLAN forwarding bridged decap
switch(config-tcam-feature-acl-port-mac)# packet ipv6 forwarding bridged
switch(config-tcam-feature-acl-port-mac)# packet ipv6 forwarding routed
switch(config-tcam-feature-acl-port-mac)# packet ipv6 forwarding routed decap
switch(config-tcam-feature-acl-port-mac)# packet ipv6 forwarding routed multicast

19.2 BGP/MPLS L3 VPN

Border Gateway Protocol/ Multiprotocol Label Switching (BGP/MPLS) L3 Virtual Private Network (VPN) allows a Service Provider (SP) or an Enterprise to provide the service of interconnecting geographically dispersed customer sites. This type of service can be provided to multiple customers over the common network backbone infrastructure of the Service Provider while performing the following tasks:

- Maintaining the privacy of each customer.
- Allowing for overlapping IP addresses among customers.
- Having constrained route distribution – only those routers in the Service Provider network that require the customer routes have them.

EOS achieves the above through the extensions to BGP as defined in *RFC 4364* for IPv4 and *RFC 4659* for IPv6, and the use of VPN Routing and Forwarding Tables (VRFs), Route Distinguishers (RDs), and Route Targets (RTs).

Configure BGP/MPLS L3 VPN using BGP in the multi-agent routing protocol model.

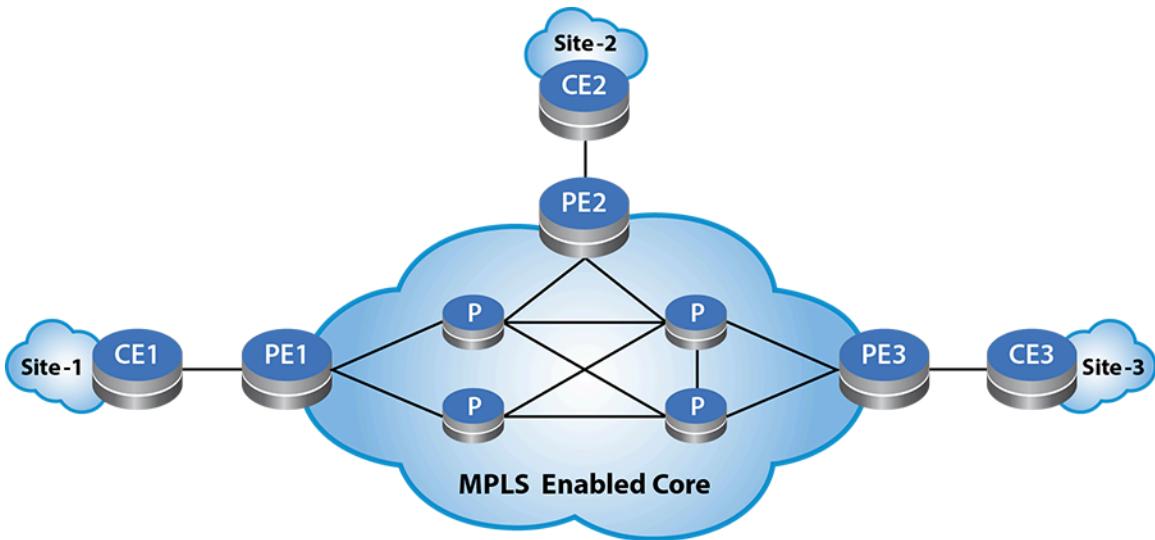

- [Overview](#)
- [Configuring BGP/MPLS L3 VPN](#)
- [Displaying BGP/MPLS L3 VPN Information](#)
- [Limitations](#)

19.2.1 Overview

A Virtual Private Network, or VPN, consists of a set of geographically dispersed sites attached to the Service Provider's (SP) backbone, with IP interconnectivity among the sites. Using this scenario, the customer can obtain "VPN service" from the SP. The SP provides a VPN service to multiple customers, using this common backbone network infrastructure. The sample VPN topology diagram illustrates three sites where a customer interconnects over the SP backbone network.

At each site, the Customer Edge router (CE) attaches to the Provider's Edge router (PE). The CE can attach to more than one PE, and in these cases, the CE becomes "multi-homed". The routers in the SP core network, without attachment to any CE, are referred to as "P" routers. The "P" routers do not know about the customer routes.

Figure 19-2: MPLS Enabled Core Schematic

The CE attaches to PE in a VRF. The routes learned from the CE program in the corresponding VRF and the PE then distributes the routes to other PEs as "VPN routes" using MP-BGP. The switch uses two new BGP address families, VPN-IPv4 (AFI=1, SAFI=128) and VPN-IPv6 (AFI=2, SAFI=128).

On the PEs, corresponding to the VPN, VRFs configure with the RD and one or more import and export RTs. The RD attaches to the customer route to create a VPN route. By picking a unique RD for each VRF and attaching it to the customer route, the VPN route becomes unique. This allows for customers with overlapping IP addresses to be managed by the Service Provider. This unique VPN route advertises to other PEs along with the configured export RT and the VPN label. The PE router allocates a VPN label per VRF and address family. The PE router programs the Label FIB (LFIB) with this label information. When the PE router receives an incoming MPLS packet with the VPN label as the topmost label, it pops the label and performs an IP lookup in the associated VRF. The PE router also maintains a mapping of import RTs to the corresponding VRFs. The switch uses the mapping when deciding into which VRFs to import a received VPN route.

The PE learns customer routes from the CE through the PE-CE routing protocol, which could be Static routing, EBGP, OSPF, or ISIS. The PE installs those customer routes in the associated VRF, with the CE as the nexthop. The customer routes in the VRF export into the BGP VPN table as VPN routes, along with the VPN label and the configured export RTs as BGP path attributes. These VPN routes then advertise to other PEs which have been activated for the VPN address-families (VPN-IPv4/VPN-IPv6). The PE then sets itself as the nexthop while advertising the VPN routes. The PE which receives those VPN routes strips out the RD and import them as IPv4 or IPv6 routes into the VRFs. The list of VRFs into which the route is imported is determined based on the mapping of import RTs to VRFs. These routes will be programmed into the FIB along with the VPN label and the remote PE as the nexthop. Once these routes install in the VRF, the CE connected to that VRF learns those routes, based on the PE-CE routing protocol, and make it available it in

the attached customer network. This way the geographically dispersed customer sites learn of each other's networks and IP reachability establishes between them.

19.2.1.1 Forwarding

In the Service Provider's core network, there should be MPLS LSPs between the PEs. The connection to the VPN next-hop should be over an MPLS tunnel. Set up the MPLS LSPs in the core using RSVP-TE or LDP in conjunction with OSPF/ISIS or ISIS-SR.

When the PE receives an IP packet from the CE destined to the remote site, it performs an IP lookup in the VRF to the connected CE. This lookup provides the VPN label to use and the next hop, the remote-PE. The switch imposes the VPN label on the IP packet and the resulting MPLS packet then tunnels through the MPLS LSP to the remote PE. As result of hop popping, the MPLS packet arrives at the remote PE with the VPN label as the topmost label. The label lookup results in popping the VPN label and an IP lookup performed in the associated VRF. Note that the PE would have programmed this label action when it allocated the label. That IP lookup results in the IP packet forwarded out to the CE.

19.2.2 Configuring BGP/MPLS Layer 3 VPN

Configuring BGP/MPLS L3 VPN requires enabling the SP core for MPLS and then configuring the PEs with the required BGP configuration.

The configuration assumes that you have enabled the SP core network for MPLS, by configuring an IGP (OSPF/ISIS) followed by a label distribution protocol such as LDP, RSVP-TE or ISIS-SR. Typically, configure loopback interfaces on all the PE and the P routers and the IGPs exchange reachability to those loopback interfaces. And then the MPLS Label Distribution Protocol sets up MPLS LSPs/tunnels between all the loopbacks.

This section includes the following topics:

- [LDP Hello Redundancy](#)
- [Enabling BGP to Exchange the Routing Tables with the Peer](#)
- [Configuring the VRF Information](#)
- [Configuring the Route Distinguisher](#)
- [Configuring Route Targets](#)
- [Configuring Import / Export Route-maps](#)
- [VPN Next-hop](#)

Use the following steps to enable MPLS and LDP on the PE:

Configure the terminal.

```
switch# configure terminal
```

Enter the **Loopback0** Interface Configuration Mode.

```
switch(config)# interface Loopback0
```

Configure the destination IP address.

```
switch(config)# ip address 11.0.0.1/32
```

Enable MPLS routing.

```
switch(config)# mpls ip
```

Configure MPLS LDP.

```
switch(config)# mpls ldp
```

Configure the router ID interface.

```
switch(config-mpls-ldp)# router-id interface Loopback0
```

Configure **no shutdown**.

```
switch# configure terminal
switch(config)# interface Loopback0
switch(config-if)# ip address 11.0.0.1/32
switch(config)# mpls ip
switch(config)# mpls ldp
switch(config-mpls-ldp)# router-id interface Loopback0
switch(config-mpls-ldp)# no shutdown
```

19.2.2.1 LDP Hello Redundancy

LDP Hello Redundancy establishes a redundant target Hello adjacency for each neighbor discovered through the Basic Discovery Mechanism using the LDP Extended Discovery mechanism. For the mechanism to work, the following must be true:

- Devices must have a loopback interface configured to serve as the transport address interface, which must be routable through all interfaces on the device.
- Devices must be reachable via a redundant path through other devices on the network.
- Both devices must have Hello Redundancy configured or the targeted Hello messages will be ignored.

After establishing a Hello adjacency using LDP Basic Discovery, devices with Hello Redundancy start sending Targeted Hello messages to the Transport Address found in the received Link Hello message of Basic Discovery. The Targeted Hello adjacency can support the session established between peers even when all Link Hello adjacencies have timed out. The FEC label bindings between two peers with no Link Hello adjacency do not become active because the Interior Gateway Protocol does not use the other peer as the next hop. Maintaining the FEC label bindings and the session between the two peers can save significant time when re-establishing the Link Hello adjacency.

The **neighbor hello-redundancy** command configures Hello Redundancy on all platforms under the LDP configuration mode. If a Link Hello adjacency restores within 600 seconds of getting lost, the switch drops the Target Hello adjacency and the session associated with it. The timeout can be configured using the **duration** option of the command. An infinite value for the **duration** disables the timeout.

Configuration for LDP Hello Redundancy

The following example applies to all platforms.

These commands enable Targeted Hello redundancy with a duration of 300 seconds.

```
switch(config-mpls-ldp)# neighbor hello-redundancy
switch(config-mpls-ldp)# neighbor hello-redundancy duration 300
```

Use either of the following commands to disable Hello Redundancy.

```
switch(config-mpls-ldp)# neighbor hello-redundancy none
switch(config-mpls-ldp)# default neighbor hello-redundancy
```

The following command shows the Targeted Hello adjacencies established.

```
switch(config)# show mpls ldp discovery detail
LDP MD5 Password Not Set
Local LDP Identifier: 2.2.2.2:0
Discovery Sources:
  Interfaces:
    Ethernet1 (ldp):

      Source IP addr: 3.3.3.3; Transport IP addr: 3.3.3.3
      Hold time: 45 sec; Proposed local/peer: 45/45 sec; Expires in: 35.89 sec
      Target configuration source: Hello Redundancy
```

19.2.2.2 Enabling BGP to Exchange the Routing Tables with the Peer

Enable the send-community extended parameter on the neighbor and allow BGP to exchange the routing tables with the peer.

- Activating the peer, the remote PE, under the **address-family VPN-IPv4** and **address-family VPN-IPv6** modes enables BGP to negotiate the MPLS L3 VPN address families.
- Specify the address for the VPN next-hop using the command, **neighbor default encapsulation mpls next-hop-self source-interface Loopback0**.

In the preceding configuration example, the system uses the address **11.0.0.1** from interface **Loopback0** as the nexthop in the VPN route advertisements.

19.2.2.3 Configuring the VRF Information

First, the VRF must be configured in the **global** mode and IPv4 and IPv6 routing must be enabled in the VRF. After that, under the **router bgp** mode, configure the VRF and provide the information related to RD and import and export RTs.

Configure terminal.

```
switch# configure terminal
```

Enable IP routing.

```
switch(config)# ip routing
```

Enable IP routing for the VRF.

```
switch(config)# ip routing vrf vrf1
```

Enable IPv6 routing for the VRF.

```
switch(config)# ipv6 unicast-routing vrf vrf1

switch# configure terminal
switch(config)# ip routing
switch(config)# ip routing vrf vrf1
switch(config)# ipv6 unicast-routing vrf vrf1
```

Display the VRF configuration information under router BGP mode.

```
switch(config-router-bgp-vrf-vrf1)# show active
router bgp 300
  vrf vrf1
    rd 11.0.0.1:0
    route-target import vpn-ipv6 300:0
    route-target import vpn-ipv4 300:0
    route-target import vpn-ipv4 300:0
    route-target import vpn-ipv4 300:0
    route-target export vpn-ipv6 300:0
    route-target export vpn-ipv4 300:0
    redistribute connected
    redistribute static
switch(config-router-bgp-vrf-vrf1) #
```

19.2.2.4 Configuring the Route Distinguisher

The Route Distinguisher (RD) has a structure that can easily be configured and managed. Configure it by specifying two fields separated by a colon, as in *administrative-subfield: assigned-number-subfield*.

The administrative subfield contains either an IP address such as the PEs loopback address or the AS number. The *assigned-number-subfield* can be any number determined by the SP. The RD must be unique per VRF. You can have overlapping address space between VRFs, but the RD ensures that a VPN route can be uniquely identified as received by a remote PE. However, the identification of which VRF(s) to import the received VPN route should be handled by the import routing tables configured on the remote PE.

19.2.2.5 Configuring Route Targets

Configure the import and export Route Target. The RTs have a structure similar to the RDs. They consist of *administrative-subfield: assigned-number-subfield*. In the example, the AS number has been used as the administrative subfield. And the value **0** has been used for the assigned number subfield. The RT plays an important role in identifying the VPN.

- Received VPN routes with the import RT as path attributes import into the VRF and have RTs with extended-community BGP path attributes. They import into VRFs which import RT configuration for RTs in the received VPN route.
- And while advertising the routes from the VRF as VPN routes, the export RT attaches to the route as an extended-community BGP attribute.
 1. In the example, the connected and static routes in the VRF redistribute into BGP. And these routes export as VPN routes.
 2. You can also have a BGP session with the CE. In that case, routes received over that session export as VPN routes. And imported routes advertise to the CE.

19.2.2.6 Configuring Import and Export Route Maps

BGP only considers the route targets referenced in the `route-target import` statement for route import. However, the routes imported into a VRF can be further controlled by applying an import route-map. And the routes exported from the VRF can be controlled by applying an export route-map. Note that the import route-map does not allow importing additional route targets. Instead, it allows more granular control of the imported routes. The same concept applies to the export route-map, and the export route-map allows more granular control of the exported routes.

Complete the following steps:

Configure the terminal.

```
switch# configure terminal
```

Configure BGP, **4274781899**.

```
switch(config)# router bgp 4274781899
```

Configure the VRF under Router BGP Configuration Mode.

```
switch(config-router-bgp)# vrf vrf1
```

Select the BGP route distinguisher, **36351:268450419**.

```
switch(config-router-bgp-vrf-vrf1)# rd 36351:268450419
```

Configure the import route-target VPN-IPv4, unicast address family, **36351:1001**.

```
switch(config-router-bgp-vrf-vrf1)# route-target import vpn-ipv4 36351:1001
```

Optionally, configure a second import route-target for VPN-IPv4 unicast address family, **36351:268450419**.

```
switch(config-router-bgp-vrf-vrf1)# route-target import vpn-ipv4 36351:268450419
```

Configure the export route-target for VPN-IPv4 unicast address family, **36351:1001**.

```
switch(config-router-bgp-vrf-vrf1)# route-target export vpn-ipv4 36351:1001
```

Configure the import route-map, **BGP-IMPORT-VRF-SERVICES**.

```
switch(config-router-bgp-vrf-vrf1)# route-target import vpn-ipv4 route-map BGP-IMPORT-VRF-SERVICES
```

Configure the export route-map, **BGP-EXPORT-VRF-VRF1**.

```
switch(config-router-bgp-vrf-vrf1)# route-target export vpn-ipv4 route-map BGP-EXPORT-VRF-VRF1
```

Optionally, redistribute connected routes in the VRF into BGP, with the associated route-map **BGP-ANNOUNCE-CONNECTED**.

```
switch(config-router-bgp-vrf-vrf1)# redistribute connected route-map BGP-ANNOUNCE-CONNECTED
```

Optionally, redistribute static routes in the VRF into BGP, with the associated route-map **BGP-ANNOUNCE-STATIC**.

```
switch(config-router-bgp-vrf-vrf1) # redistribute static route-map BGP-ANNOUNCE-STATIC
```

The import and export route-maps should be configured separately . The configuration example displays the configuration of the same route-map **BGP-IMPORT-VRF-SERVICES**.

```
switch(config-router-bgp-vrf-vrf1) # route-map BGP-IMPORT-VRF-SERVICES permit 10
switch(config-route-map-BGP-IMPORT-VRF-SERVICES) # match extcommunity SERVICES
switch(config-route-map-BGP-IMPORT-VRF-SERVICES) # match ip address prefix-list SERVICES
```

Example:

```
switch# configure terminal
switch(config) # router bgp 4274781899
switch(config-router-bgp) # vrf vrf1
switch(config-router-bgp-vrf-vrf1) # rd 36351:268450419
switch(config-router-bgp-vrf-vrf1) # route-target import vpn-ipv4 36351:1001
switch(config-router-bgp-vrf-vrf1) # route-target import vpn-ipv4 36351:268450419
switch(config-router-bgp-vrf-vrf1) # route-target export vpn-ipv4 36351:1001
switch(config-router-bgp-vrf-vrf1) # route-target import vpn-ipv4 route-map BGP-IMPORT-VR
F-SERVICES
switch(config-router-bgp-vrf-vrf1) # route-target export vpn-ipv4 route-map BGP-EXPORT-VR
F-VRF1
switch(config-router-bgp-vrf-vrf1) # redistribute connected route-map BGP-ANNOUNCE-
CONNECTED
switch(config-router-bgp-vrf-vrf1) # redistribute static route-map BGP-ANNOUNCE-STATIC
switch(config-router-bgp-vrf-vrf1) # route-map BGP-IMPORT-VRF-SERVICES permit 10
switch(config-route-map-BGP-IMPORT-VRF-SERVICES) # match extcommunity SERVICES
switch(config-route-map-BGP-IMPORT-VRF-SERVICES) # match ip address prefix-list SERVICES
```

19.2.2.7 Configuring VPN Next Hop

By default, the system uses the source address of the BGP session as the next hop in the VPN advertisements. The switch determines the source address while establishing the TCP session between the PEs. If the SP uses a different address as the VPN next-hop, then an interface with that address must be specified under the BGP address-family VPN-IPv4 or address-family VPN-IPv6 configuration modes.

```
switch(config-router-bgp) # address-family vpn-ipv4
switch(config-router-bgp-af) # neighbor 10.0.0.2 activate
switch(config-router-bgp-af) # neighbor default encapsulation mpls next-hop-self source-interface
Loopback0

switch(config-router-bgp) # address-family vpn-ipv6
switch(config-router-bgp-af) # neighbor 10.0.0.2 activate
switch(config-router-bgp-af) # neighbor default encapsulation mpls next-hop-self source-interface
Loopback0
```

Specify the interface **Loopback 0** and then the switch selects the VPN next-hop address from the interface based on the following rules:

- For VPN-IPv4, the switch selects the IPv4 address from the interface.
- For VPN-IPv6, if the interface does not have a IPv4 address, select the IPv6 address.
- For an IPv6 peer, select the IPv6 address from the interface. If the interface does not have an IPv6 address, select the IPv4 address.

For VPN-IPv6, if an IPv4 address selected as the next-hop, EOS encodes it as a IPv4-mapped IPv6 address in the VPN route advertisement.

19.2.3 LDP Pseudowire Show Commands

Use the **show patch panel** command to display the overall status of the configured pseudowire patches.

Example

```
switch# show patch panel
Patch      Connector          Status
-----
example    1: Ethernet3           Up
            2: Port-Channel12
example2   1: Ethernet1 802.1Q VLAN 100     Up
            2: LDP neighbor 1.1.1.1 PW ID 1111
example3   1: LDP neighbor 4.4.4.4 PW ID 1040   Up
            2: Ethernet2
```

Use the **show patch panel detail** command to display the detailed status of the configured pseudowire patches.

Example

```
switch# show patch panel detail
PW Fault Legend:
  ET-IN - Ethernet receive fault
  ET-OUT - Ethernet transmit fault
  TUN-IN - Tunnel receive fault
  TUN-OUT - Tunnel transmit fault
  NF - Pseudowire not forwarding (other reason)
Patch: example, Status: Up
  Connector 1: Ethernet3
    Status: Up
  Connector 2: Port-Channel12
    Status: Up
Patch: example2, Status: Up
  Connector 1: Ethernet1 802.1Q VLAN 100
    Status: Up
  Connector 2: LDP neighbor 1.1.1.1 PW ID 1111
    Status: Up
    Local MPLS label: 100032, Group ID: 0
    MTU: 9000, 802.1Q VLAN request sent: -
    Neighbor MPLS label: 900000, Group ID: 0x0
    MTU: 9000, 802.1Q VLAN request received: -
    PW type: 4 (tagged), Control word: N
    Tunnel type: LDP, Tunnel index: 198
Patch: example3, Status: Up
  Connector 1: LDP neighbor 4.4.4.4 PW ID 1040
    Status: Up
    Local MPLS label: 100002, Group ID: 0x0
    MTU: 1500, 802.1Q VLAN request sent: -
    Neighbor MPLS label: 400000, Group ID: 0x0
    MTU: 9213, 802.1Q VLAN request received: -
    PW type: 5 (raw), Control word: N
    Tunnel type: LDP, Tunnel index: 2
  Connector 2: Ethernet2
    Status: Up
```

Use the **show patch panel forwarding** command to display the forwarding information for configured pseudowire connectors.

Example

```
switch# show patch panel forwarding
Legend:
  Type - Pseudowire type: 4 (tagged)
          5 (raw)
  CW - Control word used

In/Out           Type CW VLAN Status Patch

    Label 400000, LDP Tun 2
Et3
Po2
Po2
    Et3

PW Label Out           Source Type CW Status Patch
-----+-----+-----+-----+-----+-----+
100002  Et2            LDP   5     Up   example3
100032  Et1 802.1Q VLAN 100  LDP   4     Up   example2
```

19.2.4 Limitations

- While configuring a BGP Route-Reflector for the VPN-IPv4/VPN-IPv6 address families, the route-reflector must have transport MPLS LSPs to reach the PE nexthop addresses. Even though the route-reflector may not be in the data path and does not use the transport LSPs to forward traffic, the LSPs are required in order for the BGP nexthops to be considered as reachable valid candidates in the bestpath computation.
- When configuring eBGP peers, which receive routes over an eBGP session and re-advertise the same to a different eBGP peer, next-hop-unchanged knob must be configured, so that the original nexthop is retained.
- With iBGP route-reflector topology, next-hop-self knob must not be configured.
- Even with directly connected PEs, the VPN nexthops should be the loopback on the directly connected PEs with an MPLS tunnel between them.
 - For a VPN route to be installed in the VRF, the VPN nexthop must resolve over a MPLS tunnel.
- With OSPF as the PE-CE protocol, *RFC 4576*, setting of the DN bit in the LSA, is not supported.
- Internal BGP (iBGP) as the PE-CE protocol, *RFC 6368*, is not supported.

19.3 EVPN MPLS Shared ESI Label

In a multihomed EVPN MPLS configuration, broadcast, unknown-unicast, and multicast (BUM) packets sent from a Non-Designated Forwarder (Non-DF) PE to a Designated Forwarder (DF) PE must carry the ESI label advertised by the egress DF PE. When the egress DF PE receives a packet with the advertised ESI label, it does not forward the packet on the Ethernet Segment (ES) corresponding to that ESI label. This avoids sending the packet back to the same ES where the BUM packet originated.

However, if a DF election triggers, a PE may change its role from a Non-DF to a DF. Since the DF election runs on each PE distributively, some PE(s) may not update their view of the new DF PE and doesn't add an ESI label in the BUM packet. In such a case, the BUM packets in transit may get sent back to the same ES where they originated. To overcome this, EOS includes ESI labels to Non-DF PEs as well. This shared ESI label provides a mechanism to achieve sending an ESI label to Non-DF PEs on platforms that cannot support sending different ESI labels to multihomed peers.

19.3.1 Configuring EVPN MPLS Shared ESI Label

An Ethernet-Segment (ES) must be configured with a shared-index to allocate an ESI label value based on the shared-index configuration.

Example

```
switch(config)# interface Ethernet4
switch(config-if-Et1)# switchport access vlan 1000
switch(config-if-Et1)# evpn ethernet-segment
switch(config-evpn-es)# identifier 0022:2222:2222:2222:2222
switch(config-evpn-es)# mpls shared index 100
switch(config-evpn-es)# route-target import 00:02:00:02:00:02
```

- If all PEs provisioned with the same ES carry the same shared-index value, then they allocate the same ESI label value for that Ethernet Segment.
- A consistent configuration on all PEs enables the hardware to encapsulate the ESI label on all BUM packets towards multi-homed peers. This implements split-horizon filtering during DF role change events.
- EOS uses the shared index value as an offset into the reserved **12evpn ethernet-segment** range where EOS derives the label value as follows:
 - ESI label = label-range base value + shared-index value – 1

EOS allocates the ESI labels from the **12evpn ethernet-segment** label range with the following **default configuration**:

```
switch# show running-config all
mpls label range bgp-sr 900000 65536
mpls label range dynamic 100000 262144
mpls label range isis-sr 900000 65536
mpls label range l2evpn 1036288 12288
mpls label range 12evpn ethernet-segment 1031072 1024
mpls label range sr1b 965536 65536
mpls label range static 16 99984
```

19.3.2 EVPN MPLS Shared ESI Label Show Commands

The following show command displays the operational state when EVPN MPLS shares the ESI label between all the PEs in that Ethernet-Segment:

Example

```
switch# show bgp evpn instance
EVPN instance: VLAN 1000
  Route distinguisher: 100.0.0.1:1000
  Route target import: Route-Target-AS:64500:1000
  Route target export: Route-Target-AS:64500:1000
  Service interface: VLAN-based
  Local IP address: 100.0.0.1
  Encapsulation type: MPLS
  Label allocation mode: per-instance
  MAC route label: 1040210
  IMET route label: 1042201
  AD route label: 1040210
  Local ethernet segment:
    ESI: 0022:2222:2222:2222:2222
    Interface: Ethernet4
    Mode: all-active
    State: up
    ESI label: 1031171
Shared ESI label: on
    ES-Import RT: 00:02:00:02:00:02
    Designated forwarder: 100.0.0.1
```

```
Non-Designated forwarder: 100.0.0.2
```

- Shared ESI label state for an ES is **ON** when the following conditions are satisfied.
 - ES is configured with the shared-index **mpls shared index <value>**.
 - All PEs in that ES carry the same ESI label.
- The **l2evpn shared ethernet-segment** label range space can be looked up using the command below:

```
switch# show mpls label ranges
Start      End      Size      Usage
-----
0          15       16       reserved
16         99999   99984   static mpls
100000    116383  16384   ldp (dynamic)
116384    132767  16384   bgp (dynamic)
132768    362143  229376  free (dynamic)
362144    899999  537856  unassigned
900000    965535  65536   isis-sr
900000    965535  65536   bgp-sr
965536    1031071 65536   sr1b
1031072  1032095  1024    l2evpn shared ethernet-segment
1032096   1036287  4192    unassigned
1036288   1048575  12288   l2evpn
```

19.3.3 Limitations

When the PE switch multihomes to more than six PEs and each one of those PEs has an Ethernet Segment in the shared ESI configuration, the PE switch may not be able to add the ESI label to the MPLS label stack of BUM packets ingressing on every Ethernet Segment. In such a case, the syslog message, **EVPN-3-MPLS_SHARED_ESI_HW_RESOURCE_FULL**, appears in the system logs.

19.4 LDP Pseudowire

LDP pseudowire provides support for emulating Ethernet connections over a Multiprotocol Label Switching (MPLS) network, and controlled using the extension of the MPLS Label Distribution Protocol (LDP).

The **patch panel** command allows *patching* a local interface *connector* to an LDP pseudowire *connector*, terminating on the local switch. Configure LDP pseudowire in the MPLS LDP Configuration Mode.

LDP pseudowire also supports locally patching traffic between two interfaces and configured under the **patch panel** command.

19.4.1 Configuring LDP Pseudowire

19.4.1.1 Local-Remote Patch Configuration

To configure an LDP pseudowire, complete the following task.

1. Enter the pseudowire configuration section under the **mpls ldp** configuration section, and specify an LDP pseudowire name using the **pseudowire** command. In this example, the selected LDP pseudowire name is **ldppw**.

```
switch(config)# mpls ldp
switch(config-mpls-ldp)# pseudowire
```

```
switch(config-mpls-ldp-pw) # pseudowire ldppw
```

- Once an LDP pseudowire has been configured, configure the neighbor IP address, pseudowire ID, and pseudowire MTU using the **neighbor**, **pseudowire-id**, and **mtu** configuration commands.

```
switch(config-mpls-ldp-pw-ldppw) # neighbor 1.2.3.4
switch(config-mpls-ldp-pw-ldppw) # pseudowire-id 1
switch(config-mpls-ldp-pw-ldppw) # mtu 9000
```

- To configure a cross-connection between two connectors, configure a pseudowire patch by specifying a patch name in the **patch panel** configuration section.

```
switch(config) # patch panel
switch(config-patch) # patch example
```

- After entering a **patch** configuration mode, configure a type 4 LDP pseudowire by specifying a VLAN tagged interface connector and an LDP pseudowire connector using the **connector** command.

```
switch(config-patch-example) # connector interface ethernet1 dot1q vlan 100
switch(config-patch-example) # connector pseudowire ldp ldppw
```

- After entering a **patch** configuration mode, configure a type 5 LDP pseudowire by specifying an interface connector and an LDP pseudowire connector using the **connector** command.

```
switch(config-patch-example) # connector interface ethernet1
switch(config-patch-example) # connector pseudowire ldp ldppw
```

Note: IP routing must be enabled and the interface used for the local connector must be routed.

```
switch(config) # ip routing
switch(config) # interface ethernet1
switch(config-if-Et1) # no switchport
```

19.4.1.2 Local-Local Patch Configuration

The patch can also consist of two interface connectors or two VLAN tagged interface connectors to configure local stitching.

```
switch(config-patch) # patch example
switch(config-patch-example) # connector conn1 ethernet1
switch(config-patch-example) # connector conn2 ethernet2
switch(config-patch) # patch example2
switch(config-patch-example2) # connector conn1 ethernet1 dot1q vlan 100
switch(config-patch-example2) # connector conn2 ethernet2 dot1q vlan 200
```

Note: IP routing must be enabled and both interfaces used for the local connectors must be routed.

```
switch(config) # ip routing
switch(config) # interface ethernet1
switch(config-if-Et1) # no switchport
switch(config) # interface ethernet2
switch(config-if-Et2) # no switchport
```

19.4.1.3 Additional Patch Configuration Commands

The `shutdown` configuration command can be used to disable a pseudowire patch.

Example

```
switch(config-patch-example)# shutdown
```

19.4.1.4 Forwarding Behavior For Layer 2 Control Packets

There are differences in forwarding behavior for reserved MACs between the Ethernet Tagged Mode and the Ethernet Raw Mode. Some Layer 2 control packets are terminated and consumed at the Provider Edge, while others are encapsulated and forwarded on the pseudowire. Below is a list of the common Layer 2 control packets, and a summary of their forwarding behavior.

| | Ethernet Tagged Mode (type 4) | Ethernet Raw Mode (type 5) |
|--------|---|----------------------------|
| STP | When STP is enabled, STP packets are terminated. Otherwise, they are forwarded. | Forwarded |
| LLDP | Terminated | Forwarded |
| LACP | Terminated | Terminated |
| MACsec | Not supported | Forwarded |

In addition, custom Layer 2 Control Packet forwarding behavior for type 5 pseudowire can be configured using the Layer 2 Protocol Forwarding functionality.

19.4.2 LDP Pseudowire Limitations

When a subinterface has been configured with the same VLAN tag as a pseudowire connector on the same parent interface, or vice versa, only the first configured feature will be active.

When a port-based connector is used for a pseudowire or local cross-connect patch, dot1q-tagged packets will have the outer tag incorrectly removed on ingress/encap if any one of several other features are configured on the switch (on any interface) including Layer 2 subinterfaces, Dot1q Tunnel, VLAN Mapping, and VXLAN. The only workaround is to unconfigure these other features.

When a VLAN-based connector (or subinterface with dot1q encapsulation) is used for a pseudowire or local cross-connect patch, tagged packets will have incorrect tags after forwarding if any one of several other features are configured on the switch (on any interface) including Layer 2 subinterfaces, Dot1q Tunnel, VLAN Mapping, and VXLAN. The only workaround is to unconfigure these other features.

19.4.3 LDP Pseudowire Show Commands

Use the `show patch panel` command to display the overall status of the configured pseudowire patches.

Example

```
switch# show patch panel
Patch      Connector          Status
-----  -----  -----

```

```

example    1: Ethernet3                      Up
           2: Port-Channel12
example2   1: Ethernet1 802.1Q VLAN 100      Up
           2: LDP neighbor 1.1.1.1 PW ID 1111
example3   1: LDP neighbor 4.4.4.4 PW ID 1040  Up
           2: Ethernet2

```

Use the **show patch panel detail** command to display the detailed status of the configured pseudowire patches.

Example

```

switch# show patch panel detail
PW Fault Legend:
  ET-IN - Ethernet receive fault
  ET-OUT - Ethernet transmit fault
  TUN-IN - Tunnel receive fault
  TUN-OUT - Tunnel transmit fault

19.5 LDP Entropy Label

If a network device uses deep packet inspection for load balancing, Arista Networks recommends to use entropy label in LDP to improve load balancing in MPLS networks by providing sufficient entropy in the label stack.

19.5.1 Configuring LDP Entropy Label

Use the **entropy-label** command to enable the MPLS LDP entropy labelling on the switch. Use the **no** form of the command to disable the MPLS LDP entropy labelling. By default, the entropy label knob is disabled.

```
switch# mpls ldp
switch(config-mpls-ldp)# entropy-label
switch(config-mpls-ldp)# exit
```

19.5.2 Show Commands

The **show running-config all** command displays the Entropy Label Signaling status.

```
switch# show running-config all
!
mpls ldp
...
no entropy-label
...
!
```

The **show mpls ldp bindings detail** command displays whether the ELC is advertised or not for a given FEC for both local/remote bindings.

```
switch# show mpls ldp bindings 1.1.1.1/32 detail
1.1.1.1/32
    Local binding: Label: imp-null, ELC: False
        Uptime: 1:51:14
        Advertised to: 2.2.2.2:0, 3.3.3.3:0
    Remote binding: Peer ID: 2.2.2.2:0, Label: 100001, ELC: True
        Uptime: 1:51:57
    Remote binding: Peer ID: 3.3.3.3:0, Label: 100002, ELC: True
        Uptime: 1:52:05
```

Following debug commands are modified to incorporate Entropy label and Entropy label indicator information in label stack for debugging on ingress router.

```
switch> show platform fap fec <idx>
Tunnel Type: Mpop(mpls pop), Mpush(mpls push), Mswap(mpls swap),
            MoG(mpls-over-gre), T(IPv4 tunnels GRE/VXLAN)

301 ELI EL 201',
'|0 |0.0.0.0/0 |TRAP |CoppSystemL3LpmOver|0 | - |SlowReceive | - |576815| - |',

```

19.5.3 Limitations

- When the Transit LSR is acting as a PHP hop for a given LDP tunnel with entropy label pushed onto it by an Ingress LSR, only the LDP tunnel label will be popped at PHP whenever the Egress LSR has signaled implicit-null in LDP.
- Egress LSR should be capable of handling ELI as top label in the label stack like [ELI, EL, VPN, Payload].

19.6 MPLS Commands

MPLS Commands

- **MPLS Commands**

19.6.1 authentication

Use the **authentication** command to enable cryptographic authentication. The **no** form and the **default** form of the command removes the cryptographic authentication.

Command Mode

MPLS RSVP sub-mode (mpls-rsvp)

Command Syntax

```
authentication [index 1-4294967295 [active | password ][sequence-number window 1-255][[type [md5 | none]]]
```

```
no authentication [index 1-4294967295 [active | password ][sequence-number window 1-255][[type [md5 | none]]]]
```

```
default authentication [index 1-4294967295 [active | password ][sequence-number window 1-255][[type [md5 | none]]]]
```

Parameters

- **index 1-4294967295** - Specify the password index.
 - **active** - Use index as the active password.
 - **password** - Specify the password.
- **sequence-number** - Specify the index in the sequence.
 - **window 1-255** - Configure the reorder window size. The default value is **5**. A value of **1** turns off support for packet reordering.
- **type** - Specify the authentication mechanism.
 - **md5** - Add the MD5 hash.
 - **none** - Indicates no authentication mechanism. Disables cryptographic authentication.

Examples

- Enable Cryptographic Authentication ([RFC 2747](#)) by setting the **authentication type** to **md5** and configuring an active password.

```
(config-mpls-rsvp) # authentication type md5
```

- Configure authentication secrets with an index. One of the indices should be chosen as the actively used password:

```
(config-mpls-rsvp) # authentication index 1 password s3cr3t
(config-mpls-rsvp) # authentication index 1 active
```

Use the **active** password to authenticate outgoing messages. All configured passwords are accepted for authentication of incoming packets, which allows smooth key rollover.

- Password encoding is available:

```
(config-mpls-rsvp) # authentication index 1 password 7 07092E43
```

-
- The size of the sequence number reorder window can be changed to accommodate a larger number of out-of-order packets. A value of N means that a packet is accepted if all earlier received packets with a higher sequence number are within the preceding $N-1$ packets.

```
(config-mpls-rsvp) # authentication sequence-number window 5
```

The default value is **5**. A value of **1** effectively turns off support for packet reordering.

19.6.2 cspf delay

RSVP-TE uses CSPF to compute the FRR backup path. Throttle CSPF to avoid frequent path changes when frequent network events occur. Use the `cspf delay` command to specify how frequently CSPF runs after a network event by specifying the initial wait interval, back-off interval, and maximum wait interval for CSPF. The `no` form and the `default` form of the command remove the CSPF delay.

Command Mode

Router traffic engineering mode

Command Syntax

```
cspf delay [initial n back-off n] max n
no cspf delay [initial n back-off n] max n
default cspf delay [initial n back-off n] max n
```

Parameters

- **initial** Specify initial wait interval for CSPF.
 - *n* - Specify the time in milliseconds. **1-300000**.
 - **back-off** - Specify the back-off interval for CSPF.
 - *n* - Specify the time in milliseconds. **1-300000**.
- **max** - Specify the maximum wait interval for CSPF.
 - *n* - Specify the time in milliseconds. **1-300000**.

19.6.3 entropy-label

The **entropy-label** command enables the MPLS LDP Entropy Label.

The **no entropy-label** command removes the MPLS LDP Entropy Label configurations from the ***running-config***.

Command Mode

MPLS LDP Configuration Mode

Command Syntax

```
entropy-label  
no entropy-label
```

Example

This command enables the MPLS LDP Entropy Label.

```
switch(config)# mpls ldp  
switch(config-mpls-ldp)# entropy-label  
switch(config-mpls-ldp)# exit
```

19.6.4 fast-reroute

Use the **fast-reroute** command to support Fast Reroute (FRR) link protection/NHOP (**RFC 4090**). You can enable FRR protection by setting the Fast Reroute mode to **link-protection**.

Command Mode

MPLS RSVP sub-mode (mpls-rsvp)

Command Syntax

```
fast-reroute [mode [ link-protection | node-protection | none]][reversion [global | local]]
```

Parameters

- **mode** Fast reroute mode.
 - **link-protection** - Protects against failure of the next link.
 - **node-protection** - Protects against failure of the next node.
 - **none** - Disables fast reroute.
- **reversion** Select reversion behavior.
 - **global** Global revertive repair (default).
 - **local** Local revertive repair.

Examples

- Enable support for Fast ReRoute (FRR) link protection/NHOP (**RFC 4090**) by setting the Fast Reroute mode to **link-protection**.

```
(config-mpls-rsvp) # fast-reroute mode link-protection
```

- To turn off FRR, change the mode to the default setting **none**.

```
(config-mpls-rsvp) # fast-reroute mode none
```

- You can change the revertive behavior of the FRR from the **global** revertive mode to the **local** revertive mode. In the **global** revertive mode, an LSR re-routed over a bypass tunnel because the downstream link keeps uses the bypass tunnel even after the link has recovered. This expects the headend router to set up a new LSP upon notification that a link became unavailable. In the **local** revertive mode, the LSR switches back to using the primary link after recovery.

```
(config-mpls-rsvp) # fast-reroute reversion local
```

- The default for reversion is **global**.

```
(config-mpls-rsvp) # fast-reroute reversion global
```

19.6.5 fast-reroute reversion

You can change the revertive behavior of the FRR from the **global** revertive mode to the **local** revertive mode. In the **global** revertive mode, an LSR re-routed over a bypass tunnel because the downstream link became unavailable but keeps using the bypass tunnel after the link recovers. This expects the headend router to set up a new LSP upon notification that a link became unavailable. In the **local** revertive mode, the LSR switches back to using the primary link after recovery.

The default for reversion is **global**.

Command Mode

Configuration sub-mode for RSVP

Command syntax

```
fast-reroute reversion [global | local]
```

Parameters

- **global** Global revertive repair.
- **local** Local revertive repair.

Examples

- Set the fast-reroute reversion to local:

```
(config-mpls-rsvp) # fast-reroute reversion local
```

- The default for reversion is **global**.

```
(config-mpls-rsvp) # fast-reroute reversion global
```

19.6.6 graceful-restart

The **graceful-restart** command configures Graceful Restart for RSVP which preserves data plane traffic when RSVP agents restart.

The **no** and **default** versions of the command disables the feature and removes it from the *running-config*.

Command Mode

MPLS RSVP Configuration Mode

Command Syntax

```
graceful-restart [role [helper | speaker]] [timer [recovery | restart]] [maximum timer_value]
```

Parameters

- **role** - Specify the Graceful Restart role.
 - **helper** - Assists with RSVP neighbors restarts.
 - **speaker** - Allows the local node to restart.
- **timer** - Specify the RSVP Graceful Restart time.
 - **recovery** - Specify the recover timer.
 - **restart** - Specify the restart timer.
- **maximum** -
- **timer_value** - Specify the maximum timer value as a number between 1 and 320 seconds.

Example

Use the following commands to configure a Helper role with a maximum recovery timer of 160 seconds:

```
switch(config)# mpls rsvp
switch(config-mpls-rsvp)# graceful-restart role helper
switch(config-mpls-rsvp-gr-helper)# timer recovery maximum 160 seconds
```

19.6.7 hello interval

The **hello interval** command sets the time between the hello packets. The **no** form of the command explicitly disables the Hello messages, while the **default** form of the command resets to the default setting of 10 seconds with a multiplier of 4.

Command Mode

Configuration sub-mode for RSVP.

Command Syntax

```
hello interval [interval [sec]] [multiplier [num]]  
no hello interval [interval [sec]][multiplier [num]]  
default hello interval [interval [sec]][multiplier [num]]
```

Parameters

- **interval sec** The interval in units of seconds.
 - **multiplier num** The number of missed hellos after which the neighbor is expired.

Examples

- In this example, EOS sends hello messages to all known neighbors every **10** seconds. If the switch does not receive hello responses from a neighbor for $4 \times 10 = 40$ seconds, the switch loses communication and the neighbor resets.

```
(config-mpls-rsvp) # hello interval 10 multiplier 4
```

- In this example, the default of **10** seconds with multiplier **4** resets.

```
(config-mpls-rsvp) # default hello interval
```

- in this example, explicitly disable the Hello messages.

```
(config-mpls-rsvp) # no hello interval
```

19.6.8 mpls icmp source-interface

The **mpls icmp source-interface** command permits the designation of a source interface as an IPv4 address or IPv6 address. Using the **no** parameter disables the designated interface.

Command Mode

Global Configuration

Command Syntax

```
mpls icmp [fragmentation-needed | ip | ipv6 ttl-exceeded]  
no mpls icmp [fragmentation-needed | ip | ipv6 ttl-exceeded]
```

Parameters

- **fragmentation-needed tunneling** - Specify fragmentation for larger packets and enable MPLS tunneling.
- **ip source-interface** - Specify the source interface from the list of available interfaces:
 - **Ethernet**
 - **Loopback**
 - **Management**
 - **Port-Channel**
 - **Tunnel**
 - **Vlan**
- **ipv6 source-interface**
 - **Ethernet**
 - **Loopback**
 - **Management**
 - **Port-Channel**
 - **Tunnel**
 - **Vlan**
- **ttl-exceeded tunneling** - Time-to-live exceeded in transit and enable MPLS tunneling on the switch.

Example

Use the following command to enable a source interface, Loopback0, for IPv4:

```
switch(config)#mpls icmp ip source-interface Loopback0
```

19.6.9 mpls ip

The **mpls ip** command enables MPLS routing. Multiprotocol Label Switching (MPLS) provides a networking process that avoids complex lookups in a routing table by replacing complete network addresses with short path labels for directing data packets to network nodes. MPLS data paths are serviced through a tunnel encapsulation data structure that adds four-byte label headers to packets.

The **no mpls ip** and **default mpls ip** commands disable MPLS routing by removing the **mpls ip** command from **running-config**. When MPLS routing is disabled, routed MPLS packets are dropped and all MPLS routes and adjacencies are removed. MPLS routing is disabled by default.

Command Mode

Global Configuration

Command Syntax

```
mpls ip  
no mpls ip  
default mpls ip
```

Examples

- This command enables MPLS routing. Previous commands enabled IP routing and configured MPLS static routes.

```
switch(config)# mpls ip  
switch(config)# show running-config  
  
! Command: show running-config  
  
!  
ip routing  
!  
mpls ip  
!  
mpls static top-label 3400 10.14.4.4 pop payload-type ipv4  
mpls static top-label 4400 10.15.46.45 pop payload-type ipv4  
!  
  
!  
end  
switch(config) #
```

- This command disables MPLS routing.

```
switch(config)# no mpls ip  
switch(config)# show running-config  
  
! Command: show running-config  
          <-----OUTPUT OMITTED FROM EXAMPLE----->  
!  
ip routing  
!  
mpls static top-label 3400 10.14.4.4 pop payload-type ipv4  
mpls static top-label 4400 10.15.46.45 pop payload-type ipv4  
!  
  
!  
end  
switch(config) #
```

19.6.10 mpls parsing speculative

Use the **mpls parsing speculative** command to configure parsing additional header types used by the load-balancing hash algorithm.

Command Mode

Global Configuration

Command Syntax

```
mpls parsing speculative [control-word | ethernet | ipv4 | ipv6]
```

Parameters

- **parsing** - Configure parsing of MPLS packets.
- **speculative** - Configure speculative parsing of different types of MPLS encapsulated packets for all data plane features.
- **control-word** - Enable parsing of MPLS pseudowire packets with a control word.
- **ethernet** - Enable parsing of MPLS encapsulated Ethernet packets.
- **ipv4** - Enable parsing of MPLS encapsulated IPv4 packets.
- **ipv6** - Enable parsing of MPLS encapsulated IPv6 packets.

Example

To enable MPLS speculative parsing on Ethernet packets, use the following command:

```
switch(config)#mpls parsing speculative ethernet
```

19.6.11 mpls shared index

The `mpls shared index` command configures an Ethernet-Segment (ES) shared-index to allocate an ESI label value based on the shared-index configuration.

The `no mpls shared index` command removes mpls shared index configuration from the *running-config*.

Command Mode

EVPN Ethernet-Segment Mode

Command Syntax

```
mpls shared index index-value
no mpls shared index index-value
```

Parameter

- ***index-value*** Label index value. Value ranges from **1** to **1024**.

Example

- These commands place the switch on Ethernet-Segment (ES) configuration mode and configure an MPLS shared index value of **100**.

```
switch(config)# interface Ethernet4
switch(config-if-Et1)# switchport access vlan 1000
switch(config-if-Et1)# evpn ethernet-segment
switch(config-evpn-es)# identifier 0022:2222:2222:2222:2222
switch(config-evpn-es)# mpls shared index 100
switch(config-evpn-es)# route-target import 00:02:00:02:00:02
```

19.6.12 mpls static

The `mpls static` command creates an MPLS rule that specifies the method of handling of inbound MPLS traffic. Multiprotocol Label Switching (MPLS) is a networking process that replaces complete network addresses with short path labels for directing data packets to network nodes.

Static rules specify these parameters:

- **MPLS filter:** The top-label parameter specifies the 20-bit value that the MPLS packet's top header label must match to be handled by the rule.
- **Nexthop location:** Specifies the destination nexthop address (IPv4 or IPv6) and the interface through which the switch forwards the packet.
- **MPLS action:** Specifies the MPLS label stack management action performed on the packet:
 - **pop-payload:** removes the top label from stack; this terminates an LSP (label-switched path).
 - **swap-label:** replaces top label with a specified new label; this passes a packet along an LSP.
- **Rule priority:** Specifies the rule to be used when an MPLS packet matches multiple rules.

The `no mpls static` and `default mpls static` commands delete the specified MPLS rule from ***running-config***.

- Commands that include only a top label tag remove all MPLS rules with the matching top label.
- Commands with no **PRIORITY** parameter remove all matching routes of every metric value.

Command Mode

Global Configuration

Command Syntax

```
mpls static top-label top_tag[ bgp peer [peer IP] ] [DEST_INTF] NEXTHOP_ADDR ACTION [PRIORITY]
no mpls static top-label top_tag
no mpls static top-label top_tag [DEST_INTF] NEXTHOP_ADDR ACTION [PRIORITY]
default mpls static top-label top_tag
default mpls static top-label top_tag [DEST_INTF] NEXTHOP_ADDR ACTION [PRIORITY]
```

Parameters

- ***top_tag*** Top header's label field contents. Value ranges from **0** to **1048575** (20 bits).
- BGP peer ***peer IP*** The BGP peer identifier.
- **DEST_INTF** Specifies interface through which **NEXTHOP_ADDR** is accessed. Options include:
 - **no parameter** Any interface.
 - **ethernet *e_num*** Ethernet interface specified by ***e_num***.
 - **loopback *I_num*** Loopback interface specified by ***I_num***.
 - **management *m_num*** Management interface specified by ***m_num***.
 - **port-channel *p_num*** Port-channel interface specified by ***p_num***.
 - **vlan *v_num*** VLAN interface specified by ***v_num***.
 - **VXLAN *vx_num*** VXLAN interface specified by ***vx_num***.
- **NEXTHOP_ADDR** Nexthop address for MPLS for filtered MPLS packets. Options include:
 - ***ipv4_addr*** IPv4 address.
 - ***ipv6_addr*** IPv6 address.
- **ACTION** MPLS header stack management action performed on packet. Options include:

- **pop payload-type ipv4** Removes top layer from stack. Payload is handled as IPv4 packet.
- **pop payload-type ipv6** Removes top layer from stack. Payload is handled as IPv6 packet.
- **swap-label 0 to 1048575** Replaces header label with specified label value (20 bits).
- **PRIORITY** Specifies rule priority when multiple rules match a packet. Options include:
 - **no parameter** Assigns a metric value of 100 to the rule.
 - **metric 1 to 255** Lower values denote higher priority. Value ranges from **1** to **255**.

The **mpls static** command does not support push label actions.

Examples

- These commands create an MPLS rule that matches packets with a top label value of **3400** and causes the removal of the top label from the header stack. The nexthop destination of the IPv4 payload is IP address **10.14.4.4** through Ethernet interface **3/3/3**. This rule has a metric value of **100**.

```
switch(config)# mpls static top-label 3400 ethernet 3/3/3 10.14.4.4 pop payload-type ipv4
switch(config)# show running-config

!
mpls static top-label 3400 Ethernet3/3/3 10.14.4.4 pop payload-type ipv4
!

end
switch(config)#

```

- These commands create a backup rule that forwards the packet through Ethernet interface **4/3**. This rule's metric value of **150** assigns it backup status prior to the first rule.

```
switch(config)# mpls static top-label 3400 ethernet 4/3 10.14.4.4 pop payload-type ipv4 metric
  150
switch(config)# show running-config

!
mpls static top-label 3400 Ethernet4/3 10.14.4.4 pop payload-type ipv4 metric 150
mpls static top-label 3400 Ethernet3/3/3 10.14.4.4 pop payload-type ipv4
!

<-----OUTPUT OMITTED FROM EXAMPLE----->
end
switch(config)#

```

- These commands create an MPLS rule that forwards the packet to the nexthop address through any interface.

```
switch(config)# mpls static top-label 4400 10.15.46.45 pop payload-type ipv4
switch(config)# show running-config

<-----OUTPUT OMITTED FROM EXAMPLE----->

!
mpls static top-label 3400 Ethernet4/3 10.14.4.4 pop payload-type ipv4 metric 150
mpls static top-label 3400 Ethernet3/3/3 10.14.4.4 pop payload-type ipv4
mpls static top-label 4400 10.15.46.45 pop payload-type ipv4
!

end
switch(config)#

```

- This command uses the BGP peer option to designate the nexthop..

```
switch(config)# mpls static top-label 1001 100.1.1.1 bgp peer pop payload-type ipv4
```

- When the **peer IP** is not specified, the next-hop is considered as the peer.

```
switch(config)# mpls static top-label 1002 100.1.1.2 bgp peer 100.1.1.1 pop payload-type ipv4
```

```
switch(config)# mpls static top-label 1002 100.1.1.3 bgp peer 100.1.1.1 pop payload-type ipv4
```

- Multiple nexthops can be associated with the same BGP peer by explicitly specifying the BGP peer IP. This is useful in the case of third-party nexthops.

```
switch(config)# mpls static top-label 1000 nexthop-group mygroup bgp peer 100.1.1.1 pop  
payload-type ipv4
```

19.6.13 mpls static vrf-label

Use the `mpls static vrf-label` command to configure a static VRF label route. The `no` and `default` versions of the command removes the configuration.

Command Mode

Global configuration mode

Command Syntax

```
mpls static vrf-label mpls-label [vrf vrf-name]  
no mpls static vrf-label mpls-label [vrf vrf-name]  
default mpls static vrf-label mpls-label [vrf vrf-name]
```

Parameters

- ***mpls-label*** Value of the MPLS label.
- ***vrf vrf-name*** VRF instance name.

Example

```
switch(config)# mpls static vrf-label 100 vrf default  
switch(config)# mpls static vrf-label 200 vrf v1
```

19.6.14 mpls tunnel termination

Command Mode

Global configuration mode

Command Syntax

```
mpls tunnel termination [ model [php model][[ttl [[pipe | uniform] dscp]] pipe | uniform]
no mpls tunnel termination [model [php model][[ttl [[pipe | uniform] dscp]] pipe | uniform]
default mpls tunnel termination [model [php model][[ttl [[pipe | uniform] dscp]] pipe | uniform]
```

Parameters

- **model** Tunnel termination TTL and DSCP model.
- **php** Penultimate hop popping configuration.
- **ttl** Model for TTL.
- **pipe** Preserve the inner value.
- **uniform** Propagate value from outer header.
- **dscp** mode for DSCP.

Example

```
switch(config)# mpls tunnel termination model ttl uniform dscp pipe
```

19.6.15 mpls tunnel termination (vrf qos map)

The **mpls tunnel termination (vrf qos map)** command changes configuration mode to allow the attachment of DSCP-to-traffic-class maps to specific VRFs. This is a group change command, so no changes are made to the running config until the **exit** command is issued.

MPLS tunnel termination mode has one subcommand, **vrf**. **vrf** is also a group change command, with the subcommand **qos map dscp to traffic-class**.

Command Mode

Global Configuration

Command Syntax

```
mpls tunnel termination
```

Subcommand

```
vrf
```

Example

These commands enter MPLS Tunnel Termination Configuration mode and attach the DSCP-to-traffic-class map **map1** to the VRFs **newVRF1** and **newVRF2**.

```
switch(config)# mpls tunnel termination
switch(config-mpls-tunnel-termination)# vrf newVRF1
switch(config-mpls-tunnel-termination-vrf-newVRF1)# qos map dscp to traffic-class map1
switch(config-mpls-tunnel-termination-vrf-newVRF1)# exit
switch(config-mpls-tunnel-termination)# vrf newVRF2
switch(config-mpls-tunnel-termination-vrf-newVRF2)# qos map dscp to traffic-class map1
switch(config-mpls-tunnel-termination-vrf-newVRF2)# exit
switch(config-mpls-tunnel-termination)# exit
switch(config)# exit
```

19.6.16 ping mpls rsvp session

LSP Ping allows the user to check if the remote endpoint of an RSVP session is reachable through the LSP. Running ping on an RSVP LSP creates an LSP Ping Request packet with the label programmed by RSVP and that packet will follow the MPLS path until it reaches the end of the tunnel. If the node that receives this Request is the intended destination, it replies with an RSVP Ping Reply through normal IP routing. When the source receives the Reply it indicates that there are no apparent data plane failures and that the endpoint of that LSP is reachable.

Command Mode

Configuration sub-mode for RSVP

Command Syntax

```
ping mpls rsvp session [id num | name word] [lsp | pad-reply | repeat | source | standard | tos | tos ]
```

Parameters

- **id** Specifies the session by ID
 - ***num*** RSVP session ID.
 - ***lsp*** Specifies LSP
 - **pad-reply** Indicates that the reply should copy the pad TLV.
 - **repeat** Specifies repeat count.
 - **source** Specifies source address.
 - **standard** Sets the standard to comply with.
 - **tos** Specifies ToS value.
 - **tos** Specifies MPLS traffic class field.
- **name** Specifies session by name.
 - ***word*** RSVP session name.
 - ***lsp*** Specifies LSP
 - **pad-reply** Indicates that the reply should copy the pad TLV.
 - **repeat** Specifies repeat count.
 - **source** Specifies source address.
 - **standard** Sets the standard to comply with.
 - **tos** Specifies ToS value.
 - **traffic-class** Specifies MPLS traffic class field.

Examples

- A user can invoke the ping utility for a specific LSP by using the session and LSP IDs displayed in the CLI show commands.

```
switch# ping mpls rsvp session id 1 lsp 1 repeat 3
LSP ping to RSVP session #1 LSP #1
  timeout is 5000ms, interval is 1000ms
Via 10.0.12.2, Ethernet1, label 100000
  Reply from 10.0.34.4: seq=1, time=53.294ms, success: egress ok
Via 10.0.12.2, Ethernet1, label 100000
  Reply from 10.0.34.4: seq=2, time=75.329ms, success: egress ok
Via 10.0.12.2, Ethernet1, label 100000
  Reply from 10.0.34.4: seq=3, time=85.574ms, success: egress ok

--- RSVP target fec 0.4.4.4 : lspping statistics ---
Via 10.0.12.2, Ethernet1, label 100000
  3 packets transmitted, 3 received, 0% packet loss, time 2272ms
```

```
3 received from 10.0.34.4, rtt min/max/avg 53.294/85.574/71.399 ms
```

- For the **ping mpls rsvp session** command, the argument **Lsp** is optional. If unspecified, the utility pings all LSPs within that session.

```
switch# ping mpls rsvp session id 1 repeat 2
LSP ping to RSVP session #1
    timeout is 5000ms, interval is 1000ms
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
    Reply from 10.0.34.4: seq=1, time=60.28ms, success: egress ok
LSP 2
Via 10.0.12.2, Ethernet1, label 100002
    Reply from 10.0.34.4: seq=1, time=81.701ms, success: egress ok
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
    Reply from 10.0.34.4: seq=2, time=52.807ms, success: egress ok
LSP 2
Via 10.0.12.2, Ethernet1, label 100002
    Reply from 10.0.34.4: seq=2, time=62.814ms, success: egress ok

--- RSVP target fec 0.4.4.4 : lspping statistics ---
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
    2 packets transmitted, 2 received, 0% packet loss, time 1262ms
    2 received from 10.0.34.4, rtt min/max/avg 52.807/60.280/56.544 ms

LSP 2
Via 10.0.12.2, Ethernet1, label 100002
    2 packets transmitted, 2 received, 0% packet loss, time 1262ms
    2 received from 10.0.34.4, rtt min/max/avg 62.814/81.701/72.257 ms
```

- Similarly, the session can be specified by name and the utility pings all the LSPs within that session.

```
switch# ping mpls rsvp session name Session1to4 repeat 2
LSP ping to session Session1to4
    timeout is 5000ms, interval is 1000ms

```

19.6.17 **preemption method**

The **preemption method** command enables deferred failure of RSVP-TE LSPs on link oversubscription. Use a preemption timer value to configure a delay on a transit router to support LSPs signaled with soft preemption enabled by the headend (*RFC 5712*).

The default preemption method is soft preemption with a timer value of 30 seconds.

Command Mode

Configuration sub-mode for RSVP

Command Syntax

```
preemption method [hard | soft] timer t  
no preemption method [hard | soft] timer t  
default preemption method [hard | soft] timer t
```

Parameters

- **hard** Hard preemption.
- **soft** Soft preemption.
 - **timer** Time limit for LSP teardown.
 - **t 1-65535** Timer value in units of seconds.

Examples

- In this example, the preemption method is soft preemption with a timer value of **10** seconds.

```
(config-mpls-rsvp) # preemption method soft timer 10
```

- Setting the preemption method to hard preemption results in a timer value of **0** seconds and disables the feature.

```
(config-mpls-rsvp) # preemption method hard
```

19.6.18 refresh method

Using the **refresh method** command with the **bundled** keyword enables the Refresh Overhead Reduction that supports the sending of message IDs and refreshing state with refresh messages.

Command Mode

Configuration sub-mode for RSVP

Command Syntax

```
refresh method [bundled | explicit ]
```

Parameters

- **bundled** Refresh states using message identifiers lists. This is the default setting.
- **explicit** Send each message individually.

Examples

- Use the **bundled** keyword to enable the Refresh Overhead Reduction.

```
(config-mpls-rsvp) # refresh method bundled
```

- To turn off refresh overhead reduction, use the **explicit** keyword.

```
(config-mpls-rsvp) # refresh method explicit
```

19.6.19 show mpls parsing speculative

The **show mpls parsing speculative** command displays information about the MPLS Speculative Parsing configuration.

Command Mode

Global Configuration

Command Syntax

```
show mpls parsing speculative
```

Parameters

- **parsing** - Configure parsing of MPLS packets.
- **speculative** - Configure speculative parsing of different types of MPLS encapsulated packets for all data plane features.
- **control-word** - Enable parsing MPLS pseudowire packets with a control word.
- **ethernet** - Enable parsing MPLS encapsulated Ethernet packets.
- **ipv4** - Enable parsing MPLS encapsulated IPv4 packets.
- **ipv6** - Enable parsing MPLS encapsulated IPv6 packets.

Example

Use the following command to display information about the MPLS configuration:

```
switch#show mpls parsing speculative
Packet Type      Status
-----
Control Word    disabled
Ethernet        disabled
IPv4            enabled
IPv6            enabled
```

19.6.20 show mpls route summary

The **show mpls route summary** command displays statistics about the configuration and implementation of MPLS rules.

Command Mode

EXEC

Command Syntax

```
show mpls route summary
```

Example

This command displays a summary of MPLS rule implementation.

```
switch> show mpls route summary
Number of Labels: 1 (1 unprogrammed)
Number of adjacencies in hardware: 0
Number of backup adjacencies: 2 switch>
```

19.6.21 show mpls route

The **show mpls config route** command displays the switch's MPLS static rule configuration for the specified routes and rules.

Command Mode

EXEC

Command Syntax

```
show mpls [INFO_LEVEL] route [header_label]
```

Parameters

- **INFO_LEVEL** Specifies the filters that are used to select the routes to display. Options include:
 - **no parameter** Displays routes published by the forwarding agent.
 - **config** Displays all configured routes.
 - **Ifib** Displays routes stored to the Label Forwarding Information Base (LFIB).
- **header_label** Filters routes by MPLS top header label. Options include:
 - **no parameter** Displays routes for all header values.
- **0 to 1048575** Specifies header for which command displays information.

Examples

- This command displays the MPLS rule configuration.

```
switch# show mpls config route
Codes: S - Static MPLS Route, IA - IS-IS SR Adjacency Segment,
       IP - IS-IS SR Prefix Segment, L - LDP,
       I>L - IS-IS SR Segment to LDP, L>I - LDP to IS-IS SR Segment, R - RSVP

In-Label Out-Label Metric Payload NextHop Egress-ACL Status Monitored
----- -----
1000    pop      100   ipv4    100.0.0.1 apply     up
1001    pop      100   ipv4    20.0.0.2 apply     down
1002    pop      100   ipv4    100.0.0.2 apply     down  100.0.0.2 (Bgp)
1003    pop      100   ipv4    20.0.0.2 apply     down  100.0.0.2 (Bgp)
1004    pop      100   ipv4    20.0.0.2 apply     up    20.0.0.2 (Bgp)
1005    pop      100   ipv4    30.0.0.3 apply     up    200.0.0.3 (Bgp)
```

The status could be down if either of the following is true

1. Nexthop is not resolved (**show ip route nexthop** - shows no route).
 2. The monitored BGP session is down (**show ip bgp summary** - shows the peer is not in established state).
- The following example shows that the first route is down because the BGP peer session is down.

```
switch# show mpls config route
Codes: S - Static MPLS Route, IA - IS-IS SR Adjacency Segment,
       IP - IS-IS SR Prefix Segment, L - LDP,
       I>L - IS-IS SR Segment to LDP, L>I - LDP to IS-IS SR Segment, R - RSVP

In-Label Out-Label Metric Payload NextHop Egress-ACL Status Monitored
----- -----
88886    pop      100   ipv4    14.0.0.4 apply     down  14.0.0.4 (BGP)
88887    pop      100   ipv4    15.0.0.5 apply     down
```

- The following example shows the status of label **88886** is down because the BGP peer session to **14.0.0.4** is down, but route exists for **14.0.0.4**.

```

switch# show ip bgp summary
BGP summary information for VRF default
Router identifier 3.0.1.3, local AS number 3000
Neighbor Status Codes: m - Under maintenance
  Neighbor V AS          MsgRcvd  MsgSent  InQ OutQ Up/Down State    PfxRcd PfxAcc
  14.0.0.4 4 4000          16       18      0     0 01:04:42 Active

switch# show ip route 14.0.0.4

VRF: default
Codes: C - connected, S - static, K - kernel,
O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,

N2 - OSPF NSSA external type2, B - Other BGP Routes,
B I - iBGP, B E - eBGP, R - RIP, I L1 - IS-IS level 1,
I L2 - IS-IS level 2, O3 - OSPFv3, A B - BGP Aggregate,
A O - OSPF Summary, NG - Nexthop Group Static Route,
V - VXLAN Control Service, M - Martian,
DH - DHCP client installed default route,
DP - Dynamic Policy Route, L - VRF Leaked,
G - gRIBI, RC - Route Cache Route

S          14.0.0.4/32 [1/0] via 2.0.1.4, Ethernet2

```

19.6.22 show mpls tunnel termination qos maps

The `show mpls tunnel termination qos maps` command shows the DSCP to TC map associated with each VRF, or with a specified VRF.

Command Mode

Privileged EXEC mode

Command Syntax

```
show mpls tunnel termination qos maps [vrf vrf_name]
```

Parameter

vrf_name The VRF whose DSCP to TC map association is to be shown. If this parameter is omitted, all DSCP to TC maps associated with a VRF are shown.

Examples

This command shows the DSCP to TC maps associated with VRFs.

```
switch# show mpls tunnel termination qos maps
VRF newVRF1 DSCP to TC map: map1
VRF newVRF2 DSCP to TC map: map1 switch#
```

This command shows the DSCP to TC map associated with VRF **newVRF2**.

```
switch# show mpls tunnel termination qos maps vrf newVRF2
VRF newVRF2 DSCP to TC map: map1 switch#
```

19.6.23 show traffic-engineering cspf path

Use the `show traffic-engineering cspf path` command to display all the paths counted by CSPF.

Command Mode

EXEC

Command Syntax

```
show traffic-engineering cspf path [destination-IP]detail
```

Parameters

- **A.B.C.D** CSPF path to this destination IP address.
- **detail** Show detailed path information.

Examples

- In this example, the CSPF destination path **20.0.0.1** is selected to display.

```
switch> show traffic-engineering cspf path 20.0.0.1

Destination      Constraint                      Path
20.0.0.1        exclude Ethernet1              0.1.1.1
                  exclude SRLG of Ethernet1       0.1.1.2
                                              0.2.2.2
                                              3.3.3.2
                  exclude Ethernet2              0.1.1.1
                                              0.1.1.2
                                              0.2.2.2
                                              3.3.3.2
```

- In this example, the CSPF destination path **20.0.0.1** is selected to display detailed information.

```
switch> show traffic-engineering cspf path 20.0.0.1 detail

Destination: 20.0.0.1
Path Constraint: exclude Ethernet1
                  exclude SRLG of Ethernet1: orange-link (500),
                                              green-link (400), 100, red-link (200), 600
Request Sequence number: 1

3.3.3.2
```

19.6.24 show traffic-engineering database

Use the **show traffic-engineering database** to display the topology used for CSPF computations. Starting from *EOS Release 4.23.1F*, the SRLG group details of a neighbor are shown if it is advertised.

Command Mode

EXEC

Command Syntax

```
show traffic-engineering database
```

Special Considerations

- Beginning with *EOS Release 4.23.1F*, the SRLG group details of a neighbor are shown if it is advertised.
- Beginning with *EOS Release 4.24.2F*, information for the OSPFv2 topology is displayed if configured.

Example

```
switch# show traffic-engineering database

TE Router-ID: 1.0.0.2
  Source: IS-IS Level-1 IPv4 Topology Database

```

19.6.25 shutdown

The **shutdown** command disables the RSVP-TE protocol instance or the RSVP-related functions for the interface. The RSVP-TE configuration information associated with the interface is retained.

RSVP-TE is enabled globally by issuing **no shutdown** in the configuration sub-mode. This is the only mandatory setting for RSVP-TE to work. There is no per-interface knob to enable or disable RSVP. However, RSVP is only enabled on interfaces on which MPLS is enabled.

Command Mode

Configuration sub-mode for RSVP

Command Syntax

```
shutdown  
no shutdown
```

Examples

- You can enable RSVP-TE globally by issuing the **no shutdown** command.

```
(config-mpls-rsvp) # no shutdown
```

- Similarly, it is disabled with the **shutdown** command, which is the default.

```
(config-mpls-rsvp) # shutdown
```

19.6.26 srlg

The **srlg** command specifies if link SRLGs of a primary LSP are to be considered as constraints while creating a fast-reroute bypass tunnel with either link or node protection. When the **srlg** command is specified with **strict** keyword, then when a path for a bypass tunnel excluding SRLGs of next-hop interface of primary LSP can not be found, RSVP does not setup the bypass tunnel. When the **srlg** command is specified without the **strict** keyword, then a bypass tunnel is setup with as many links as possible that exclude the SRLGs of next-hop interface of primary LSP and where such links are not available, links that have the least number of SRLGs which are to be excluded are used.

When this CLI is not configured, the behavior remains the same as before, which is to turn off SRLG processing. Therefore, the **no** and **default** versions of the command takes you back to the default of SRLG processing being turned off.

Command Mode

Configuration sub-mode for RSVP

Command Syntax

```
srlg strict  
no srlg strict  
default srlg strict
```

Parameters

strict Applies strict SRLG constraints.

Example

The SRLGs of an interface can be configured using the following traffic-engineering CLIs.

```
switch(config)# interface Et1  
switch(config-if-Et1)# traffic-engineering srlg 100  
  
switch(config)# interface Et2  
switch(config-if-Et2)# traffic-engineering srlg 200
```

19.6.27 vrf (MPLS tunnel termination)

The **vrf (MPLS tunnel termination)** command places the switch in MPLS Tunnel Termination VRF Configuration mode. There is one command available in this mode: [qos map dscp to traffic-class \(MPLS tunnel termination VRF\)](#).

Command Mode

MPLS Tunnel Termination Configuration mode

Command Syntax

vrf vrf_name

Parameter

vrf_name The name of the VRF to configure. This does not create a VRF. The VRF must be created with the **vrf** command in Configuration mode.

Example

These commands place the switch in MPLS Tunnel Termination VRF Configuration mode for VRF **newVRF1**.

```
switch(config)# mpls tunnel configuration
switch(config-mpls-tunnel-configuration)# vrf newVRF1
switch(config-mpls-tunnel-configuration-vrf-newVRF1) #
```

Resource Reservation Protocol for Traffic Engineering (RSVP-TE)

The Resource Reservation Protocol for Traffic Engineering (RSVP-TE) distributes Multiprotocol Label Switching (MPLS) labels for steering traffic and reserving bandwidth.

The following features are supported:

- RSVP-TE Core Protocol and ingress, egress, and transit roles
- Hello Messages
- Refresh Overhead Reduction
- Cryptographic Authentication
- Fast Reroute with link and node protection support (facility backup)
- LSP Ping and Traceroute
- Bandwidth Management
- SRLG for Fast Reroute Bypasses
- MTU Signaling
- Soft Preemption
- Support for OSPFv2 and IS-IS as the IGP
- Point to Multipoint (P2MP) Label Switched Paths (LSPs)

The RSVP section includes:

- [RSVP-TE Overview](#)
- [LDP over RSVP](#)
- [Configuring RSVP-TE](#)
- [RSVP-TE Commands](#)

20.1 RSVP-TE Overview

- Resource Reservation Protocol for Traffic Engineering (RSVP-TE) includes the following:
 - **RSVP-TE Label Edge Router (LER)** implements the headend functionality for the ingress router, and at times, the egress router.
 - **RSVP-TE Label Switching Router (LSR)** applies functionality for the transit router.
 - **RSVP-TE P2MP LER** adds ingress and egress support for Point-to-Multipoint (P2MP) LSPs to be used in a Multicast Virtual Private Network (MVPN) as an extension to the LSR support, which adds transit support.
 - **RSVP-TE P2MP LSR** adds transit support for Point-to-Multipoint (P2MP) LSPs.

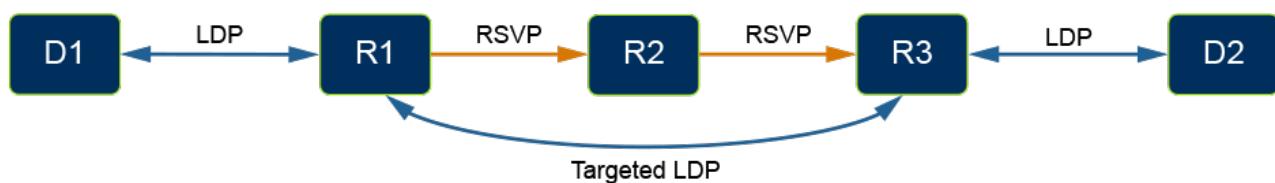

20.2 LDP over RSVP

LSPs formed by LDP normally follow IGP routing. The LDP speaker selects the downstream LSR for a particular prefix as the LDP peer that advertises it with the best IGP metric using the interface address, which is the IGP next hop for the prefix. However, there are cases where it is desirable to use either a non-adjacent router as the next hop, or use a different adjacent router as the LDP next hop rather than the IGP next hop. An example is tunneling LDP traffic over a mesh of RSVP tunnels in a WAN core to take advantage of traffic engineering capabilities in RSVP. In these situations, LDP over RSVP can be used to direct the LDP traffic flow.

Non-adjacent LDP Neighbors

The diagram below shows a case where the downstream LSR for the D2 prefix does not exist at R1 because not all routers in the network are LDP speakers. Specifically R2 would be the IGP next hop for D2 from R1, but R2 does not run LDP. In this situation, a targeted LDP adjacency is used to establish an LDP session between R1 and R3. With LDP tunneling enabled on the RSVP tunnel from R1 to R3 via R2, R1 is able to use R3 as the downstream LSR for the D2 prefix. A single end-to-end LDP LSP is now established from D1 to D2.

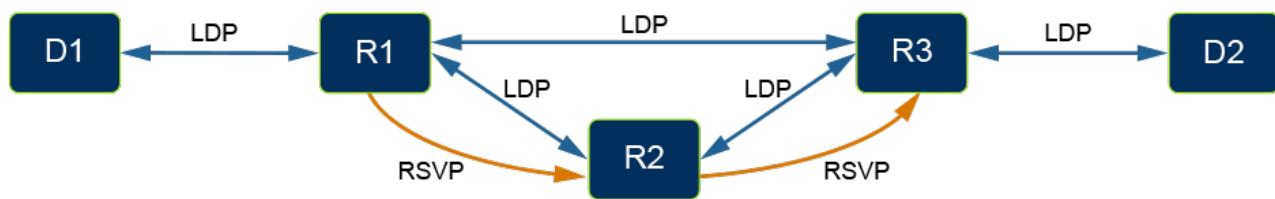

Figure 20-1: Non-adjacent LDP Neighbors

Forcing Traffic Off the IGP Path

LDP over RSVP can also be used to force LDP traffic over a preferred path other than that given by the IGP. The following diagram shows such a scenario where the IGP next hop for the D2 prefix from R1 is R3. All routers are LDP speakers so R3 could be used as the downstream LSR for the D2 prefix at R1, but the path via R2 is preferred. Enabling LDP tunneling on R1 to R3 via R2 will force the LDP traffic over the RSVP tunnel. When available, RSVP tunnels are always selected by the implementation over IGP next hops. In either case, R3 is the downstream LSR from R1. The choice is on the path taken.

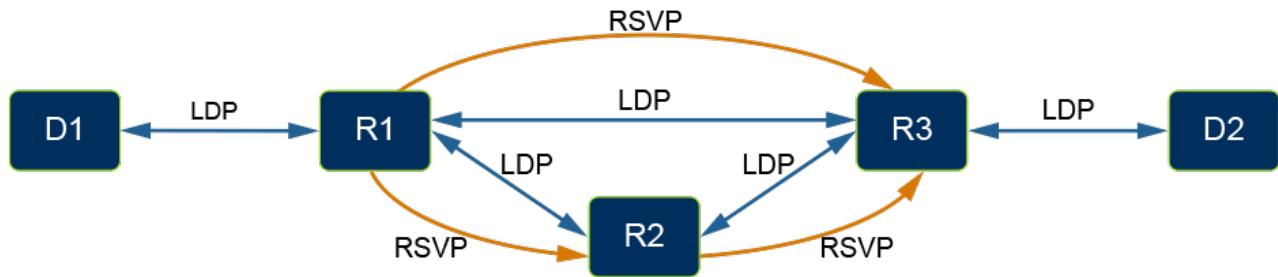

Figure 20-2: Forcing Traffic Off the IGP Path

Multi-path Routing

LDP over RSVP will leverage multiple configured RSVP tunnels when the tunnels have the same endpoint. LDP traffic will use ECMP across the selected tunnels. In the following diagram, traffic from R1 to D2 may use either the direct RSVP tunnel from R1 to R3 or the RSVP tunnel from R1 to R3 via R2.

Figure 20-3: Multi-path Routing

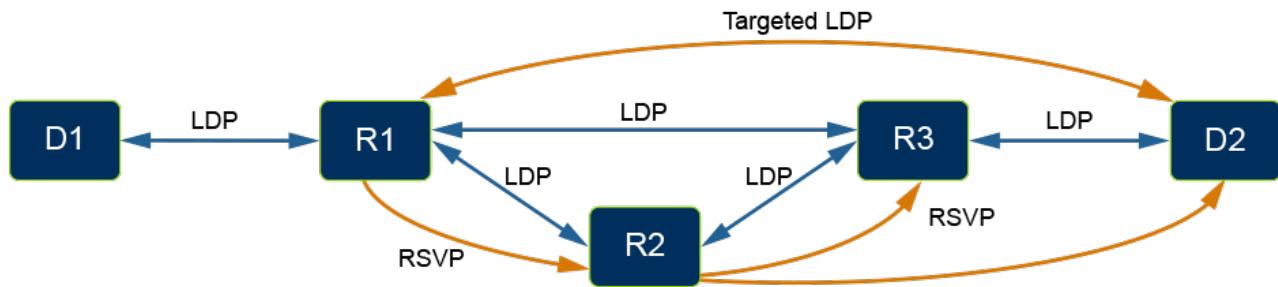

RSVP Tunnel Selection

LDP over RSVP selects RSVP tunnels such that the loop-free condition is guaranteed and the tunnel with the closest endpoint to the destination is always used. To expand on the previous examples, if an RSVP tunnel existed from R1 to D2 via R2 (skipping R3) then it would be used instead of the tunnel from R1 to R3 via R2. ECMP would not be used between the two tunnels because they do not have the same endpoint.

There is a potential problem with RSVP tunnels to non-adjacent routers. With the new RSVP tunnel to D2, R1 will not have a downstream LSR for the D2 prefix unless it has an LDP session with D2. Therefore, a targeted LDP adjacency is required between R1 and D2. This is similar to the situation where an LSR does not have a downstream router for a prefix because it does not have an LDP session with the IGP next hop.

Figure 20-4: RSVP Tunnel Selection

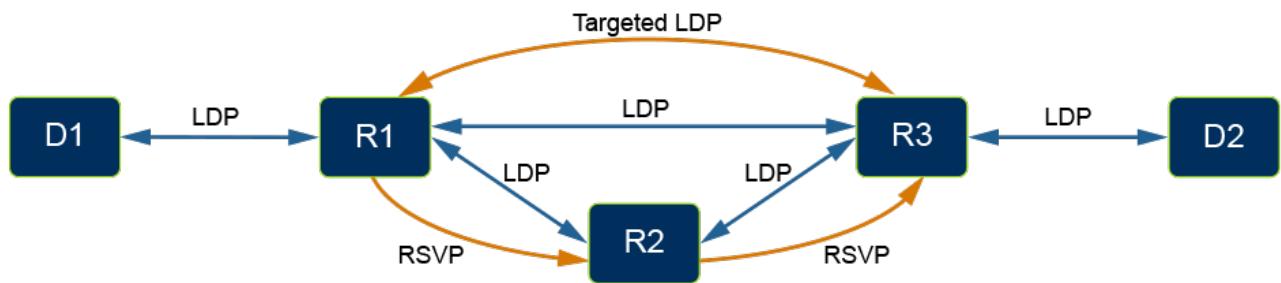

Protecting Against Link Failure

RSVP protection mechanisms can be used to protect the LDP over RSVP data path against link or node failures. However a link failure may also cause an LDP session to go down which would then disrupt the LDP data path. To protect the LDP control plane it is recommended that an LDP Hello Redundancy configuration is used with LDP over RSVP when the routers are adjacent. Hello Redundancy automatically establishes a targeted adjacency with LDP peers for which a link adjacency exists. Targeted adjacencies can be automatically established with RSVP tunnel endpoint LSRs, for tunnels that have LDP tunneling enabled. There is no need to configure Hello Redundancy. Refer to the section [Automatic targeted adjacencies](#) for details.

In the following diagram, a targeted adjacency is established between R1 and R3. If the link between R1 and R3 were to fail the LDP session would continue to be supported by the targeted adjacency and LDP data traffic would continue to use the RSVP tunnel from R1 to R3 via R2. If the redundant targeted adjacency did not exist in this scenario, R1 would lose the LDP session with R3 and the IGP next hop for the D2 prefix at R1 would change to R2. LDP traffic would stop using the RSVP tunnel, and the LFIB would need to be re-programmed using the new route, disrupting LDP data traffic.

When Hello Redundancy is used to protect against link failure with LDP over RSVP it is suggested to configure an infinite duration because data traffic may continue in this state indefinitely. This is unlike normal LDP where a non-adjacent LSR cannot be used as a downstream router. In that case Hello Redundancy is only preserving the control plane in case the failed link recovers.

Figure 20-5: Protecting Against Link Failure

Automatic Targeted Adjacencies

The RSVP tunnel configuration is leveraged to establish LDP targeted adjacencies automatically between LSRs are the endpoints of an RSVP tunnel with LDP tunneling enabled. This feature requires that the RSVP tunnel source and destination addresses are configured to be the same as the LDP transport addresses for the LSRs. If that is not the case, then targeted adjacencies should be configured either through a static configuration or by using Hello Redundancy.

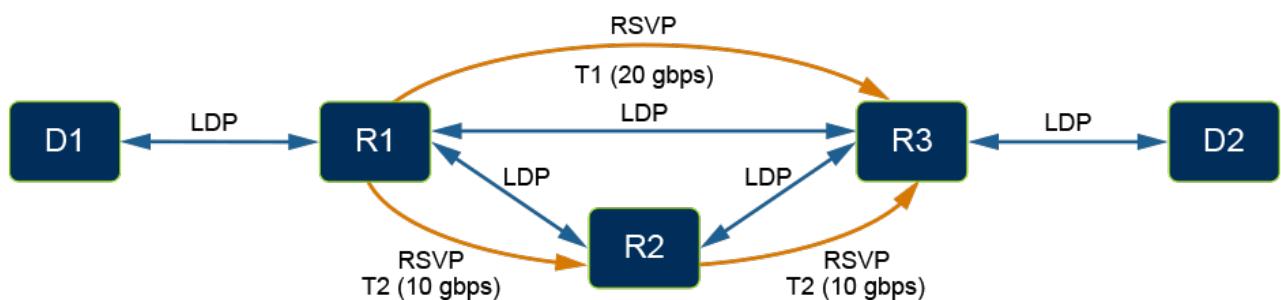

UCMP

Load balance traffic to prefixes in the ratio of bandwidths can be configured on RSVP tunnels. In the following diagram, T1 is a direct 20 Gbps tunnel from R1 to R3. T2 is another 10 Gbps RSVP tunnel to R3 with a hop at R2. With UCMP for LDP tunneling configuration, traffic from R1 to D2 would be load balanced in the ratio of the bandwidths on the two RSVP tunnels and as a result, tunnel T1 would carry twice as much traffic as tunnel T2.

Note: Load balancing in the ratio of specified bandwidths is only done across tunnels destined to the same tunnel endpoint.

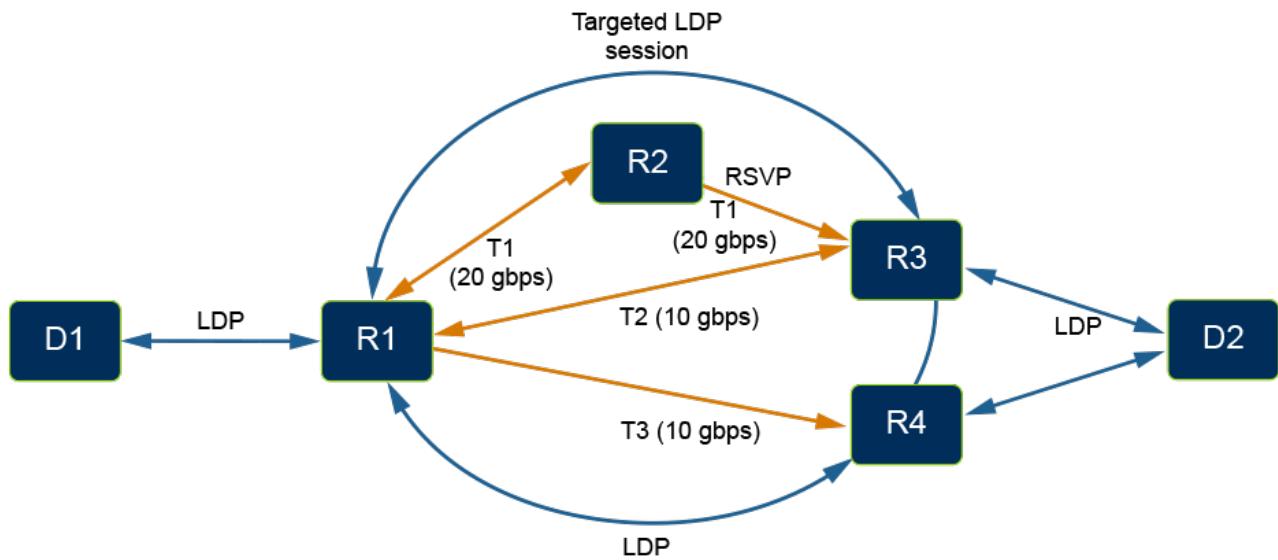

Figure 20-6: UCMP Example 1

In the following example, D2 is reachable via RSVP tunnels to multiple tunnel endpoints R3 and R4. With UCMP and bandwidth configuration on all RSVP tunnels, traffic to D2 from R1 will be equally distributed to R3 and R4. Further, traffic destined to R3 is load balanced in the ratio of the specified bandwidths. For example,

if the bandwidths on the tunnels are as specified in the figure above and there is 6 Gbps traffic to D2 from R1, tunnels T1, T2 and T3 would carry 2 Gbps, 1 Gbps, and 3 Gbps, respectively.

Figure 20-7: UCMP Example 2

20.3 Configuring RSVP-TE

The configuration of RSVP-TE requires the configuration of one or more of the following:

- [Configuring RSVP-TE LER](#)
- [Configuring RSVP-TE LSR](#)
- [Configuring RSVP-TE P2MP LER](#)
- [Configuring RSVP-TE P2MP LSR](#)

20.3.1 Configuring RSVP-TE LER

Enable the dedicated RSVP-TE LER configuration mode by entering the [router traffic-engineering – not an RSVP command](#) to enter the router traffic-engineering mode and then the [rsvp](#) command to enter the RSVP sub-mode.

```
switch# config
switch(config) # router traffic-engineering
switch(config-te) # rsvp
switch(config-te-rsvp) #
```

In this submode, the configuration has three components for P2P tunnels:

- **Global configuration:** All settings apply to all configured tunnels.
- **Path specifications:** Describes a set of constraints for paths.
- **Tunnel specifications:** Describes which path each tunnel can take. Also includes per-tunnel configuration, fast-reroute, metric, and profiles.

Configuration Example

1. Enable IP routing.

```
switch(config) # ip routing
switch(config) #
```

2. Before starting RSVP-TE, make sure that MPLS is enabled ([add x-ref to MPLS section 19.1](#)) and a local interface is used to derive the source IP address for RSVP-TE tunnels.

Note: This is a mandatory setting.

```
switch(config-te-rsvp) # local-interface Loopback 0
```

3. ISIS or OSPF needs to be enabled for traffic-engineering. For more information about ISIS, refer to ([add x-ref to section 15.4](#)):

```
switch(config) # router isis 1
switch(config-router-isis) #traffic-engineering
switch(config-router-isis-te) # no shutdown
switch(config-router-isis-te) # is-type level-2
```

4. MPLS interfaces have to be enabled globally for traffic-engineering by issuing `no shutdown` in the configuration sub-mode.

```
switch(config) # mpls rsvp
```

```
switch(config-mpls-rsvp) # no shutdown
```

5. RSVP-TE is enabled globally by issuing **no shutdown** in the configuration sub-mode.

```
switch(config) # router traffic-engineering
switch(config-te) # rsvp
switch(config-te-rsvp) # no shutdown
```

Note: Additional LER configurations may be configured, since they apply to all tunnels by default, but can then typically be overridden by the tunnel. These include **FRR mode**, **SRLG mode**, **preemption timers**, **GR/HR settings**, **MTU signaling**, **CSPF ECMP tie-break settings**, and **lsp self-ping**. More information is available in [RSVP-TE Commands](#).

Path Specifications

Path specifications can be explicit or dynamic. Dynamic uses a Constrained Shortest Path First (CSPF) search procedure to find a path in the network topology known to the headend. A path specification of a certain name can only either be explicit or dynamic.

Explicit Path Specifications

In an explicit path specification, the operator provides all hops in the path. The given path is used directly as the Explicit Route Object (ERO) in RSVP Path messages. All hops are implicitly strict hops. Explicit loose hops are not supported.

The **explicit** submode is used to configure explicit paths.

```
switch(config-te-rsvp) # path MyPath explicit
switch(config-te-rsvp-path-expl-MyPath) #
```

Each hop is specified explicitly in order.

```
switch(config-te-rsvp-path-expl-MyPath) # hop 10.0.12.2
switch(config-te-rsvp-path-expl-MyPath) # hop 10.0.34.4
```

The **before** and **after** keywords allow the insertion of new hops in any existing path by indicating the relative position. This unique internal ordering will be displayed when using the **show running-config** command.

```
switch(config-te-rsvp-path-expl-MyPath) # hop 10.0.23.3 before 10.0.34.4
switch(config-te-rsvp-path-expl-MyPath) # hop 10.0.45.5 after 10.0.34.4
```

A hop can be removed using the keyword **no** **hop**.

```
switch(config-te-rsvp-path-expl-MyPath) # no hop 10.0.12.2
```

Dynamic Path Specifications

A dynamic path specification requires the constraints with which a CSPF procedure finds a path in the network topology. Effectively, the path specification serves as a template to get instantiated together with other tunnel constraints. The CSPF result is a list of strict hops that form the Explicit Route Object (ERO).

The **dynamic** submode is used to configure dynamic paths.

```
switch(config-te-rsvp) # path MyPath dynamic
switch(config-te-rsvp-path-dyn-MyPath) #
```

The keyword **exclude** specifies that CSPF must not choose the specified address on the path. Each exclude hop expresses that neither end of a link in the path may have the specified address.

Note: Other interfaces on the same node may be used.

```
switch(config-te-rsvp-path-dyn-MyPath) # hop 10.0.56.6 exclude
```

The keyword **include** specifies that it must be included in the computed path in a certain order. By default, a hop is strict, meaning that it must appear directly after the previously specified hop. A hop can be loose, allowing other hops to be filled by the CSPF procedure.

```
switch(config-te-rsvp-path-dyn-MyPath) # hop 10.0.56.6 include
```

The keyword **administrative-group** can be specified to restrict CSPF paths to links that match a set of admin groups. Their IDs are globally significant, and the specification contains lists and ranges of admin groups to include or exclude. Every chosen link for a dynamic path must be in all of the admin groups specified in the **include all** range, must be in one of the admin groups specified in the **include any** range and not in any of those in the **exclude** range. The admin group range starts at 0 and ends at 31.

```
switch(config-te-rsvp-path-dyn-MyPath) # administrative-group include all 1
include any 2-4 exclude 7,9
```

Administrative groups can be specified using a name as an alias mapped to a numerical value. The mapping can be configured in global TE mode. Please refer to [IS-IS Traffic-Engineering TOI](#) for details.

These names can be directly used to configure administrative group constraints in addition to the numerical format. The list of administrative groups should be comma-separated without spaces.

```
switch(config-te-rsvp-path-dyn-MyPath) # administrative-group include all blue
include any 2-4,red exclude green,7
```

Tunnel specifications

Tunnel specification has its own submode **tunnel**.

```
switch(config-te-rsvp) # tunnel MyTunnel
switch(config-te-rsvp-tunnel-MyTunnel) #
```

Basic Tunnel Configuration

Each tunnel must have a tunnel destination IP.

```
switch(config-te-rsvp-tunnel-MyTunnel) # destination ip 10.2.2.2
```

Adding Path Specifications

A tunnel needs to specify the path on which its LSPs should be established. For this, a path specification is referenced by its name, which configures the primary LSP.

```
switch(config-te-rsvp-tunnel-MyTunnel) # path MyPath
```

A secondary LSP may be specified, providing a fallback in case the primary LSP is not available. The secondary LSP is either established on-demand (cold standby) once the primary is unavailable or pre-signaled (hot standby). Configuring a secondary path is optional.

Note: Only one secondary path can be configured per tunnel.

```
switch(config-te-rsvp-tunnel-MyTunnel) # path MyOtherPath secondary pre-signaled
```

Bandwidth Specification

A tunnel can be used to reserve bandwidth along the path with an explicit configuration. Available units are bps, kbps, mbps, and gbps. By default, no bandwidth reservation is signalled.

```
switch(config-te-rsvp-tunnel-myTunnel)# bandwidth 10 mbps
```

An alternative to explicit bandwidth configuration is the **auto** command, which specifies the minimum and maximum bandwidth for the tunnel and adjusts bandwidth with an adjustment period based on the observed traffic. The adjustment period is an optional parameter measured in seconds. The default adjustment period is 0, meaning the algorithm decides when to adjust bandwidth.

```
switch(config-te-rsvp-tunnel-myTunnel)# bandwidth auto min 1 mbps max 5 mbps  
adjustment-period 60
```

Tunnel priorities

Setup and hold priorities from 0 to 7 can be configured for the tunnel, where 0 means most preferred and 7 means least preferred.

 **Note:** The hold priority should have a lower value (more preferred) than the setup priority to avoid cycles where an LSP is continuously established and immediately preempted.

```
switch(config-te-rsvp-tunnel-myTunnel)# priority setup 5 hold 3
```

Color Attributes

A color attribute can be assigned to publish the tunnel to the `system-colored-tunnel-rib` instead of the `system-tunnel-rib`. This helps in steering traffic into the tunnel.

 **Note:** This color attribute is strictly a local attribute.

```
switch(config-te-rsvp-tunnel-myTunnel)# color 60
```

Enabling the Tunnel

Tunnels are not enabled by default. It must be enabled using the **no shutdown** command to leave the tunnel sub-mode.

```
switch(config-te-rsvp-tunnel-MyTunnel)# no shutdown
```

 **Note:** None of the per-tunnel settings take effect if a command other than **no shutdown** is used to leave the tunnel sub-mode. This includes **exit**. Use **abort** to cancel all changes and leave the command mode.

To view the active configuration, use the **show active** command. To view the pending configuration, use the **show pending** command. To view the differences between the active and the pending configurations, use the **show diff** command.

Tunnel Participation in IGP Shortcuts and LDP over RSVP

To specify an RSVP tunnel to participate in IGP shortcuts, use the **igp shortcut** command.

```
switch(config-te-rsvp-tunnel-MyTunnel)# igp shortcut
```

 **Note:** Refer to the [IGP Shortcut in ISIS TOI](#) for more information.

LDP traffic can be tunneled through RSVP-TE tunnels by enabling the **tunneling ldp** command.

```
switch(config-te-rsvp-tunnel-MyTunnel) # tunneling ldp
```

UCMP with LDP over RSVP can be configured using the **tunneling ldp ucmp** command.

```
switch(config-te-rsvp-tunnel-MyTunnel) # tunneling ldp ucmp
```

Note: Refer to the [LDP over RSVP TOI](#) for more information.

Tunnel Optimization

Periodic tunnel optimization can be configured globally or individually for a specific tunnel. The optimization interval is configured in **config-te-rsvp** mode for global periodic tunnel optimization..

```
switch(config-te-rsvp) # optimization interval 3600 seconds
```

Optimization can also be disabled on a specific tunnel. If optimization needs to be enabled for all the tunnels with a common interval, but disabled on a specific tunnel, use the following commands.

```
switch(config-te-rsvp) # optimization interval 3600 seconds
switch(config-te-rsvp) # tunnel myTunnel
switch(config-te-rsvp-tunnel-myTunnel) # optimization disabled
```

Tunnel Endpoint Aliases

Configuring alias IPv4 and IPv6 endpoints per tunnel allows these additional next hops to be resolved using the existing tunnel. Up to 15 alias endpoints can be configured per tunnel.

```
switch(config-te-rsvp-tunnel-myTunnel) # alias endpoint 5.5.5.5
switch(config-te-rsvp-tunnel-myTunnel) # alias endpoint 2001::10
```

Split-Tunnel

RSVP split-tunnel allows splitting the bandwidth for a tunnel between multiple sessions. With this feature enabled, RSVP will automatically create multiple LSPs with smaller bandwidth reservations for a single tunnel.

```
switch(config-te-rsvp-tunnel-myTunnel) # split-tunnel quantum 10 kbps
switch(config-te-rsvp-tunnel-myTunnel) # split-tunnel quantum 10 kbps sub-
tunnels limit 20
```

Adaptive Split-Tunnel

The RSVP adaptive split-tunnel feature allows each sub-tunnel to grow and shrink based on measured bandwidth. Configuring the adaptive split-tunnel feature is done by configuring the min/max with the split-tunnel configuration. Each sub-tunnel grows and shrinks between these values, as opposed to being of a fixed size in the regular split tunnel case.

Note: Adaptive split-tunnels cannot be configured with explicit fixed bandwidth configuration, and instead, auto-bandwidth must always be used.

```
switch(config-te-rsvp-tunnel-myTunnel) # split-tunnel min 1 gbps max 50 gbps
```

If the bandwidth has been reduced enough that it can be satisfied by fewer sub-tunnels than what currently exists, sub-tunnels will not be deleted immediately. There is a delay after which these extra sub-tunnels get removed. This reduction-delay is configurable and has a default value of 1 hour.

```
switch(config-te-rsvp-tunnel-myTunnel)# split-tunnel min 1 gbps max 50 gbps  
reduction-delay 30 minutes  
switch(config-te-rsvp-tunnel-myTunnel)# split-tunnel min 1 gbps max 50 gbps  
reduction-delay 15 seconds  
switch(config-te-rsvp-tunnel-myTunnel)# split-tunnel min 1 gbps max 50 gbps  
reduction-delay 12 hours
```

The limit on the number of sub-tunnels is also configurable. Even if the last computed bandwidth requires more sub-tunnels, the number will be capped at that limit. The default limit is 10.

```
switch(config-te-rsvp-tunnel-myTunnel)# split-tunnel min 1 gbps max 50 gbps  
sub-tunnels limit 10
```

Tunnel Metric

The tunnel metric feature is used to configure a per RSVP tunnel metric so that specific tunnels to a TEP can take precedence over other tunnels to the same TEP when forming ECMP. The tunnel metric is published to the tunnel RIB to be considered for BGP cost calculations.

```
switch(config-te-rsvp-tunnel-myTunnel)# metric 10
```

A dynamic metric mode that follows the IGP metric is also available.

```
switch(config-te-rsvp-tunnel-myTunnel)# metric igrp
```

20.3.2 Configuring RSVP-TE LSR

Basic Configuration

1. The device needs to be in the [mpls rsvp](#) mode.

Enter the MPLS RSVP configuration Mode:

```
switch(config)# mpls rsvp  
switch(config-mpls-rsvp)#{
```

2. Enable RSVP-TE globally by issuing the [no shutdown](#) command in the MPLS RSVP configuration mode.

```
switch(config-mpls-rsvp)# no shutdown
```

3. Configure the state [refresh interval](#). This affects how often state refresh messages are sent. The interval parameter is in seconds. The default value is **30** seconds.

```
switch(config-mpls-rsvp)# refresh interval 30
```

4. Configure the [hello interval](#). In the following example, the hello messages are sent to all known neighbors every **10** seconds. If no hello responses are received from a neighbor for the period of the interval multiplied by the multiplier value ($4 \times 10 = 40$ seconds), the configuration loses connectivity and resets the neighbor. Hellos are one way to determine that a neighbor is unreachable, BFD can also be used.

Note: Configuring the [hello interval](#) is optional.

```
switch(config-mpls-rsvp)# hello interval 10 multiplier 4
```

5. Configure the refresh method, which supports sending message IDs and refreshing state with Srefresh messages. This is an optional configuration setting which reduces signaling overhead at high scale. When the Srefresh method is set to **bundled**, it enables Refresh Overhead Reduction which supports sending message IDs and refreshing state with Srefresh messages.

```
switch(config-mpls-rsvp) # refresh method bundled
```

The following sections describe some of the many configuration settings available. For a list of all available RSVP-TE commands refer to [RSVP-TE Commands](#).

Configuring Traffic Engineering

For CSPF to compute the FRR backup path to a particular destination, enable traffic engineering on all the IGP-enabled interfaces, and globally enable the traffic engineering extensions. For IS-IS, enable under the **Router ISIS** configuration mode, for OSPFv2, enable in the **Router OSPFv2** configuration mode. This is required for the IGP to start exchanging TE-related attributes with peers and build the topology database.

In addition, CSPF needs a router ID to uniquely identify a router, so it can find a path to it. CSPF also uses its own router-id as a source for running SPF. So a router-id is required to be configured under **router traffic-engineering** mode for CSPF to function properly.

Cryptographic Authentication Extension

Enable Cryptographic Authentication by configuring the **authentication type** to **md5** and adding an active password.

```
switch(config-mpls-rsvp) # authentication type md5
```

Authentication secrets are configured with an index. The index refers to the globally configured list of authentication passwords. Select one of the indices as the password:

```
switch(config-mpls-rsvp) # authentication index 1 password s3cr3t
switch(config-mpls-rsvp) # authentication index 1 active
```

The **active** password is used to authenticate outgoing messages. Authentication of all incoming packets accepts all configured passwords, allowing smooth key rollover.

Configuring Fast Reroute Extension

This setting applies to the Point of Local Repair (PLR) behavior. The router may be a PLR if it is the upstream node relative to a protected link or node for routing an LSP. Merge Point (MP) behavior is not affected by this setting. In addition to affecting PLR behaviour, if the node is the headend for LSPs this also determines which local-protection mode is requested by the LSP.

Enable Fast ReRoute (FRR) link protection by setting the **Fast Reroute** mode to **link-protection**.

```
switch(config-mpls-rsvp) # fast-reroute mode link-protection
```

Enable Node Protection using the parameter **node-protection**. Available options include:

- **link-protection** which protects against failure of the next link.
- **Node-protection** protects against failure of the next node.
- **None** disables fast reroute.

You can change the reversion behavior of FRR from **global revertive** mode to the **local revertive** mode. An LSR reroutes over a bypass tunnel because the downstream link failed. With **global reversion** the LSR will keep using the bypass tunnel to reroute traffic for the affected LSPs, even if the link recovers. This expects the headend router to set up a new LSP upon notification that a link is no longer available. With **local reversion**, the LSR switches back to using the primary link after recovery.

Note: Node protection will always use global reversion on the PLR, even if local reversion is configured

```
switch(config-mpls-rsvp) # fast-reroute reversion local
```

Note: The default for reversion is **global**.

Administrative Group Constraints for Bypass LSPs

Administrative group constraints restrict CSPF path computation to links that match a set of administrative groups. When specified for an interface, they apply to all LSPs bypassing that interface, including link and node protection.

[Administrative group](#) constraints can be configured for interfaces using the following command from the interface config mode:

```
switch(config) # interface Et1
switch(config-if-Et1) # rsvp bypass administrative-group include all 1 include
any 2-4 exclude 7,9
```

The list of administrative groups should be provided as a comma-separated input without spaces.

Administrative group constraints are represented with a single 512-bit value, where each bit represents a single admin group, supporting administrative groups in the range of 0 to 511. Administrative groups can also be directly specified in the command in hexadecimal format, where each bit represents a single admin group:

```
switch(config-if-Et1) # rsvp bypass administrative-group exclude 0x280
```

Note: The hexadecimal format is limited to a 32-bit value, and thus can only specify admin groups in the 0-31 range.

Administrative group constraints can be specified using the **administrative-group alias ALIAS group VALUE** command in the **router traffic-engineering** mode. These names can be directly used to configure administrative group constraints in addition to the existing numerical format in the range of 0-511:

```
switch(config-if-Et1) # rsvp bypass administrative-group include all blue
include any 2-4,red exclude green,7
```

Configuring Shared Risk Link Groups

The **srlg** command specifies if the link SRLGs of a primary LSP can be considered as constraints when creating a fast-reroute bypass tunnel with either link or node protection. When using **srlg** with the **strict** keyword, and if a path for a bypass tunnel excluding SRLGs of the next-hop interface of primary LSP can not be found, RSVP does not setup the bypass tunnel. When the **srlg** command is used without the **strict** keyword, a bypass tunnel is set up with as many links as possible that exclude the SRLGs of the primary LSP.

```
switch(config-mpls-rsvp) # srlg
```

If not configured, the behavior remains the same, SRLG processing is turned off . The **no** and **default** versions of the command return to the default of behavior no SRLG processing.

The CSPF path selection process will choose the path where the shared unique Shared Risk Link Groups (SRLGs) have the lowest cost. This is to enable users to quantify the risk of a particular SRLG in their network. This is configured using the **cost** keyword followed by the desired cost as a number between

1-4294967295. If no cost is specified for an SRLG, it will have the default cost of 100. Without any costs configured, the CSPF path selection process will behave as before and choose the path with the fewest shared SRLGs.

The SRLGs of an interface can be configured using the following commands:

```
switch(config) # interface Et1
switch(config-if-Et1) # traffic-engineering srlg 100 cost 300

switch(config) # interface Et2
switch(config-if-Et2) # traffic-engineering srlg 200 cost 100
```

Note: Although many of SRLGs can be configured on an interface, Constrained Shortest Path First (CSPF) only considers a maximum of **16** SRLGs for finding a path with SRLG constraints.

Configuring Constrained Shortest Path First (CSPF)

RSVP-TE uses CSPF to compute the FRR backup path. CSPF can be configured to avoid frequent path changes when frequent events occur on the network. Use the Router Traffic Engineering configuration mode to specify how frequently CSPF runs after a network event by specifying the initial wait interval, back-off interval, and maximum wait interval for CSPF. Use the following commands to configure CSPF to an initial wait interval of 200 milliseconds, a back-off interval of 400 milliseconds, and a maximum wait interval of 2000 milliseconds:

```
switch(config) # router traffic-engineering
switch(config-te) # cspf delay initial 200 back-off 400 max 2000
```

The switch defaults to **100** for the initial wait interval, **200** for the back-off interval, and **1000** for the maximum wait interval with all values in milliseconds.

Configuring MTU Signaling

RSVP can discover the lowest Maximum Transmission Unit (MTU) used along an LSP by evaluating and updating the MTU at each hop on which MTU signaling is enabled. The MTU will still be updated at other nodes in the path that have MTU signaling enabled. Additionally, if MTU signaling is not enabled at the headend then MTU signaling is not done at all for the LSP.

```
switch(config-mpls-rsvp) # mtu signaling
```

Configuring a Preemption Method

The preemption method is configured using the `preemption method` command. Soft preemption enables the deferred failure of RSVP-TE LSPs on a link oversubscription. Configure a preemption timer value to create a delay on a transit router to support LSPs signaled with soft preemption enabled by the headend. The default timer value is **30** seconds. The delay is the waiting period before tearing down the LSP.

The following example uses the `preemption method soft timer` command to configure the preemption method as soft preemption with a timer value of **10** seconds.

```
switch(config-mpls-rsvp) # preemption method soft timer 10
```

The alternative is hard preemption. Setting the preemption method to `hard` preemption results in a timer value of 0 seconds and disables the soft preemption feature.

Configuring Graceful Restart

Graceful Restart preserves data plane traffic when the RSVP agents restart and has two modes:

- **Helper Mode** Only helps to restart RSVP neighbors.

- **Speaker Mode** Allows the local node to restart.

If the Hello Messages feature is not enabled, Graceful Restart will be inactive. RSVP nodes participating in Graceful Restart exchange a new object in their Hello messages that advertise both Graceful Restart phases time values: the restart phase and the recovery phase.

The restart phase starts when a Hello Message times out, which marks the end of an RSVP neighbor communication. If a neighbor advertises a non-zero restart time value, a timer starts after detecting a communication loss from that neighbor.

- If an RSVP node does not receive a Hello Message from a neighbor before the end of the restart phase, Hello communication loss procedures begin on the network.
- If an RSVP node receives a Hello message with the same source instance before the end of the restart phase, the network returns to a normal RSVP state.
- If an RSVP node receives a Hello message from a neighbor with a different source instance before the recovery period starts, with a non-zero recovery value in the message, RSVP considers the neighbor as restarted, and a recovery phase begins.

Note: Path and Resv messages are paused during the restart phase.

During the recovery phase, outgoing RSVP reservation messages toward that neighbor pause until a path message for the same LSP is received **from** that neighbor. At the end of the recovery period, RSVP clears any data plane and control plane states from that neighbor not re-advertised since the restart of the RSVP neighbor.

The following is an example of configuring **Helper Mode**.

```
switch(config) # mpls rsvp
switch(config-mpls-rsvp) # graceful-restart role helper
switch(config-mpls-rsvp-gr-helper) # timer restart maximum 160 seconds
switch(config-mpls-rsvp-gr-helper) # timer recovery maximum 320 seconds
```

Note: Graceful Restart does not support Fast-Reroute events during the restart or recovery phases.

Configuring Speaker Mode

Use the following commands to enable Speaker mode and configure the requested restart and recovery values.

```
switch(config) # mpls rsvp
switch(config-mpls-rsvp) # graceful-restart role speaker
switch(config-mpls-rsvp-gr-speaker) # timer restart 160 seconds
switch(config-mpls-rsvp-gr-speaker) # timer recovery 320 seconds
```

Configuring Hitless Restart

Similar to the Graceful Restart feature, but without any communication with RSVP neighbors, Hitless Restart allows the RSVP agents to be restarted without any data plane interruptions. There are no standard procedures for this, and for this reason, if Hello messages are enabled, any restart taking longer than the configured timeout for Hello messages will result in the communication detected as lost by the RSVP neighbors of the local node.

Hitless Restart does not have any restart phase, as this phase is only meaningful for the neighbors of a restarting node. It only has a recovery period, during which it will preserve the existing installed RSVP states, until either those RSVP states are refreshed by its neighbors through usual RSVP mechanisms, or until the recovery period ends, at which points those states will be cleared.

Hitless Restart allows the RSVP agents to be restarted without any data plane interruptions. The neighbors of a restarting node using Hitless Restart do not have any way of telling that the local node has restarted, and the source instance used in Hello messages will stay the same across restarts. By default, the recovery period is set to 90 seconds.

```
switch(config-mpls-rsvp) # hitless-restart
```

The recovery period is configurable under the RSVP Hitless Restart configuration mode.

```
switch(config-mpls-rsvp-hr) # timer recovery 40 seconds
```

Explicit-Null

The RSVP explicit-null feature enables an egress LSR to advertise IPv4 explicit-null label (Label 0) to its upstream router. By default, an egress LSR always advertises implicit-null (Label 3), but that can be changed using the command.

```
switch(config-mpls-rsvp) # label local-termination explicit-null
```

Sample Configuration

```
ip routing
!
mpls ip
!
interface Ethernet1
    no switchport
    ip address 10.0.0.1/24
    isis enable instance1
    traffic-engineering
        traffic-engineering bandwidth 100 percent
        traffic-engineering metric 5
    !
router traffic-engineering
    router-id ipv4 1.1.1.1
!
router isis instance1
    net 49.0000.0000.0000.1111.00
    is-type level-2
    !
    address-family ipv4 unicast
        maximum-paths 32
    !
    traffic-engineering
        no shutdown
        is-type level-2
    !
mpls rsvp
    no shutdown
    refresh interval 60
    refresh method bundled
    hello interval 10 multiplier 4
    authentication type md5
    authentication sequence-number window 5
    authentication index 1 password 7 141A0B1B0D17393C2B3A37
    authentication index 1 active
    neighbor 1.2.3.4 authentication index 1 active
    fast-reroute mode link-protection
    fast-reroute reversion global
```

```
fast-reroute bypass tunnel optimization interval 3600 seconds
srlg strict
label local-termination explicit-null
preemption method soft timer 30
mtu signaling
```

20.3.3 Configuring RSVP-TE P2MP LER

RSVP-TE P2MP LER adds ingress and egress support for Point-to-Multipoint (P2MP) LSPs to be used in Multicast Virtual Private Network (MVPN) as an extension of the LSR support which adds transit support.

There are two major parts to the configuration: BGP and RSVP.

BGP Configuration

To enable MVPN using an RSVP P2MP tunnel, the default encapsulation can be set to `mpls protocol rsvp p2mp`. An `RSVP P2MP tunnel` profile can be configured for the VRF, as shown in the following example. It can also be configured for all VRFs under the `address-family mvpn-ipv4` config mode within `router bgp`.

```
switch# config
switch(config)# router bgp
switch(config-router-bgp)# show active
router bgp 100
    neighbor 4.4.4.4 remote-as 100
    neighbor 4.4.4.4 update-source Loopback0
    neighbor 4.4.4.4 send-community extended
    neighbor 5.5.5.5 remote-as 100
    neighbor 5.5.5.5 update-source Loopback0
    neighbor 5.5.5.5 send-community extended
!
address-family mvpn-ipv4
    neighbor 4.4.4.4 activate
    neighbor 5.5.5.5 activate
    neighbor default encapsulation mpls protocol rsvp p2mp
!
address-family vpn-ipv4
    neighbor 4.4.4.4 activate
    neighbor 5.5.5.5 activate
!
vrf red
    rd 1:1
    route-target import vpn-ipv4 100:1
    route-target export vpn-ipv4 100:1
    network 11.0.0.0/24
!
mvpn-ipv4
    rsvp p2mp tunnel profile MyProfile
```

If the tunnel profile is not configured, then an implicit `default profile` is used, which does not contain any other configuration options, as shown in the following example.

```
switch# config
switch(config)# router bgp
switch(config-router-bgp)# vrf red
switch(config-router-bgp-vrf-red)# mvpn-ipv4
aip1(config-mvpn-ipv4-vrf-red)# show active
router bgp 1
    vrf red
```

```
mvpn-ipv4
  pmsi-tunnel protocol rsvp p2mp
```

A VRF specific PMI tunnel can be configured using the command **pmsi-tunnel protocol rsvp p2mp**.

Configuring RSVP

Enable RSVP P2MP signaling functionality, which is done by entering the **p2mp** submode.

```
switch# config
switch(config)# mpls rsvp
switch(config-mpls-rsvp)# no shutdown
switch(config-mpls-rsvp)# p2mp
switch(config-mpls-rsvp-p2mp) #
```

Enable Fast Re-Route (FRR) in the **mpls rsvp** configuration mode on LER.

 **Note:** For P2MP, only link protection is supported. Even if node protection is configured, it will mean that for P2P LSPs (LER/LSR), node protection will be requested and used if available and successfully created, but for P2MP LSPs, only link protection is supported.

```
switch(config-mpls-rsvp)# fast-reroute mode link-protection
switch(config-mpls-rsvp) #
```

The tunnel profile associated with the VRF above in the BGP configuration must be defined in the **rsvp** submode of **router traffic-engineering** as follows.

```
switch(config)# router traffic-engineering
switch(config-te)# rsvp
switch(config-te-rsvp)# show active
router traffic-engineering
  rsvp
    tree ExpTree explicit
      leaf 4.4.4.4
        hop 2.2.2.2 node
        hop 4.4.4.4 node
      !
      leaf 5.5.5.5
        hop 10.0.12.2
        hop 4.4.4.4 node
        hop 5.5.5.5 node
      !
    !
    tunnel profile MyProfile p2mp
      tree ExpTree
switch(config-te-rsvp) #
```

This profile will serve as a template for all tunnels requested from BGP for VRFs that are configured to use this profile.

 **Note:** Only destinations requested by BGP will actually be signaled as part of the RSVP P2MP tunnel.

Explicit Tree Specification

The configuration example above configures an explicit tree specification called **ExpTree**. For each leaf, each hop in the path to reach the leaf from the root needs to be explicitly configured. Any leaf that is not present in the explicit tree specification will not be part of the tunnel and will not be signaled.

By default, the configured IP of the hop must be the ingress IP interface of the node. Alternatively, a node hop can be specified using the **node** keyword, which allows the path to traverse any link to the specified node. IPs specified with the **node** keyword can be ingress addresses or TE router IDs. Node and non-node hops can be mixed for the same leaf, as in the example.

Dynamic Tree Specification

Alternatively, a Dynamic Tree Specification can be configured. A dynamic tree specification delegates the discovery of the tree to a CSPF run, allowing CSPF to find paths from the root to all leaves. A dynamic tree specification does not need to contain all leaves that are part of the tree. Tree-level constraints can be in the form of administrative group constraints.

The following example directs CSPF to only consider links that do not contain the administrative group associated with name **red**, and administrative group **10**. As with P2P tunnels, administrative group constraints **exclude**, **include all**, and **include any** are supported and can be mixed freely.

```
switch(config) # router traffic-engineering
switch(config-te) # rsvp
switch(config-te-rsvp) # show active
router traffic-engineering
    rsvp
        tree DynTree dynamic
            administrative-group exclude red,10
        !
        tunnel profile MyProfile p2mp
            tree DynTree
switch(config-te-rsvp) #
```

Default Tree Specification

If a tunnel profile does not specify the name of a tree specification then a **default dynamic tree specification** is applied. This is equivalent to configuring an empty dynamic tree specification, meaning the specification has no constraints. In this case, CSPF is used to find the paths to all leaves and can use any link because of the lack of constraints.

Interoperability

Routers from other vendors may not support signaling of multiple sub-LSPs per sub-group. A compatibility configuration option is available to limit sub-group size. That setting may need to be set to 1 for interoperability with routers from some other vendors.

Note: Signaling and processing are less efficient with a smaller sub-group size. The default is 20.

```
switch# config
switch(config) # mpls rsvp
switch(config-mpls-rsvp) # p2mp
switch(config-mpls-rsvp-p2mp) # sub-group limit 1 sub-lsps
switch(config-mpls-rsvp-p2mp) # exit
switch(config-mpls-rsvp) #
```

20.3.4 Configuring RSVP-TE P2MP LSR

RSVP-TE P2MP LSR adds transit support for Point-to-Multipoint (P2MP) LSPs. Specifically, the feature adds protocol support for the transit role.

RSVP P2MP functionality is enabled by entering the `p2mp` submode.

```
switch# config
switch(config)# mpls rsvp
switch(config-mpls-rsvp)# no shutdown
switch(config-mpls-rsvp)# p2mp
switch(config-mpls-rsvp-p2mp) #
```

P2MP functionality is disabled by issuing the `disabled` command in the `p2mp` submode.

```
switch(config-mpls-rsvp-p2mp) # disabled
switch(config-mpls-rsvp-p2mp) #
```

Note: By default without the `disabled` command, P2MP is enabled as long as the mode is configured.

Use the same configuration methods and commands as RSVP-TE LSR. Refer to [Configuring RSVP-TE LSR](#) for more information.

20.3.5 Class Based Forwarding for MPLS Labeled Packets

Class Based Forwarding (CBF) provides a means for forwarding traffic through selected tunnels based on the traffic class of the incoming packet. CBF supports forwarding MPLS labeled traffic based on the EXP value in the incoming packet or the internal traffic class (TC) resolved from the parameters of the packet (e.g TC derived from EXP bits combined with port trust mode). Here, EXP bits refer to the Experimental bits in the MPLS header.

This feature enables a Label Switched Router, to steer labeled traffic (that has specific EXP values) into colored RSVP-TE tunnels. These colored tunnels are identified as follows:

1. The EXP value in the payload is mapped to a TC. The TC is mapped to a color via configuration.
2. Among RSVP tunnels configured with the mapped colors identified above, a suitable tunnel that terminates on the shortest path to the resolved destination is identified.

Traffic to that very label that does not have the EXP bits corresponding to a configured color-tc map is steered through an RSVP-TE tunnel mapped to a default color or an uncolored tunnel. If neither of those are available, the traffic will be steered through any available hop by hop path.

MPLS CBF can be configured on a headend node to allow different flows bound to the same endpoint to be steered into different paths. There are a few conditions required for CBF to use colored RSVP TE tunnels.

1. The RSVP-TE tunnel must be colored.
2. The RSVP-TE tunnels must be enabled for **tunneling ldp**, and must terminate on a node that is on the shortest path to the LDP destination.
3. **Color-TC** mapping must be configured for the associated color.
4. All the RSVP-TE tunnels to be considered for an LSP endpoint must terminate on the same node. Colored tunnels terminating on the nodes other than the node nearest to the destination are filtered out.

Fallback Precedence

Traffic that matches a colored tunnel will be steered through the colored tunnel, but traffic that does not match a configured/up colored tunnel will be steered through the default tunnel. In case a default colored tunnel or an uncolored tunnel are not available, a colored tunnel can be used as the default FEC by enabling **fallback-highest-colored-tunnel** knob. In this case, the highest colored tunnel among the tunnels to a given destination is chosen for forwarding traffic that doesn't match any specified TC in the TC->color configuration.

20.3.5.1 Configuring Class Based Forwarding for MPLS Labeled Packets

This section provides an example for LDP CBF and an example for ISIS-SR CBF.

Configuration example for LDP CBF

Configuring MPLS CBF involves four major steps and one optional configuration.

1. Configuring colored LDP-over-RSVP-TE tunnels.

```
switch(config)# router traffic-engineering
switch(config-te)# rsvp
switch(config-te-rsvp)# tunnel MyTunnel
switch(config-te-rsvp-tunnel-myTunnel)# color 60
switch(config-te-rsvp-tunnel-myTunnel)# tunneling ldp
```

2. Enable MPLS CBF with LDP-over-RSVP-TE colored tunnels.

```
switch(config)# router traffic-engineering
switch(config-te)# class-based-forwarding
```

```
switch(config-te-cbf) # forwarding-plane mpls  
switch(config-te-cbf-mpls) # tunneling ldp
```

- ### **3. Configure EXP to TC mappings.**

```
switch(config)# qos map exp 2 to traffic-class 4
```

- #### 4. Color/TC mappings.

```
switch(config)# router traffic-engineering
switch(config-te)# class-based-forwarding
switch(config-te-cbf)# color-tc-mappings
switch(config-te-cbf-color-tc)# color 100 ?
    default          Associate the specified color with any unmapped traffic
class values
    traffic-class   Map the specified color to specific traffic class values
```

5. Enable knob to choose highest colored tunnel as default FEC. This is an optional config which is useful in cases where a default colored tunnel or an uncolored tunnel are not available. When enabled, the highest colored tunnel can then be chosen for the default FEC.

```
switch(config)# router traffic-engineering
switch(config-te)# class-based-forwarding
switch(config-te-cbf)# forwarding-plane mpls
switch(config-te-cbf-mpls)# color default fallback highest
```

Configuration example for ISIS-SR CBF

1. Configure tunnels with color and enable IGP-Shortcut over RSVP-TE.

```
switch(config)# router traffic-engineering
switch(config-te)# rsvp
switch(config-te-rsvp)# tunnel MyTunnel
switch(config-te-rsvp-tunnel-myTunnel)# color 60
switch(config-te-rsvp-tunnel-myTunnel)# iqp shortcut
```

- ## 2. Enable MPLS CBF with ISIS-SR over RSVP-TE colored tunnels:

```
switch(config)# router traffic-engineering
switch(config-te)# class-based-forwarding
switch(config-te-cbf)# forwarding-plane mpls
switch(config-te-cbf-mpls)# tunneling segment-routing
```

- ### **3. Configure EXP to TC mappings.**

```
switch(config)# qos map exp 2 to traffic-class 4
```

- #### 4. Color/TC mappings.

```
switch(config)# router traffic-engineering
switch(config-te)# class-based-forwarding
switch(config-te-cbf)# color-tc-mappings
switch(config-te-cbf-color-tc)# color 100 ?
    default          Associate the specified color with any unmapped traffic
    class values
    traffic-class   Map the specified color to specific traffic class values
```

-
5. Enable knob to choose highest colored tunnel as default FEC. This is an optional config which is useful in cases where a default colored tunnel or an uncolored tunnel are not available. When enabled, the highest colored tunnel can then be chosen for the default FEC.

```
switch(config) # router traffic-engineering
switch(config-te) # class-based-forwarding
switch(config-te-cbf) # forwarding-plane mpls
switch(config-te-cbf-mpls) # color default fallback highest
```

Platform Configuration

CBF for MPLS labeled packets requires use of an appropriate TCAM profile. The [mpls-pbr-match](#) profile supports this feature. If this profile is not sufficient, please open a case with Arista support for a profile that supports your needs.

Limitations

- CBF is only supported in the default VRF.
- CBF does not support graceful restart.
- PBR takes precedence over CBF.
- The FEC Override Table supports up to 2048 entries per TCAM bank. A maximum of $12 \times 2048 = 24576$ override entries can be present if all available TCAM banks are used exclusively for CBF. 'show hardware capacity' can be used to determine the exact maximum scale limitations for different platforms.
- ECMP is supported for MPLS CBF, i.e. if there are multiple colored tunnel endpoints for a given default LfibViaSet associated with a particular TC, we only use one of the colored tunnel endpoints. It is also suggested in case we have tunnels with the same color but different endpoints.
- CBF does not apply to MPLS routes with the "pop" action such as penultimate hop pop. Any routes with the pop action will follow the default FEC and will not use the colored tunnels.
- TC can be only set based on the EXP bits. QOS / traffic-policies that modify TC cannot modify the TC of the packet that was originally derived from the EXP - TC mapping on the device.
- CBF for ISIS-SR is only supported for IPv4 prefixes and not IPv6 prefixes.
- IPv6 Support can get enabled if they share same default fec with IPv4.

20.4 RSVP-TE Commands

RSVP-TE LSR Commands

- authentication index
- authentication sequence-number window
- authentication type
- clear mpls rsvp counters
- clear mpls rsvp session
- cspf delay
- fast-reroute bypass tunnel optimization interval
- fast-reroute mode
- fast-reroute reversion
- graceful-restart role
- hardware next-hop fast-failover
- hello interval
- hitless-restart
- label local-termination
- mpls rsvp
- mtu signaling
- neighbor authentication index
- neighbor authentication type
- ping mpls rsvp session
- preemption method
- refresh interval
- refresh method
- rsvp bypass administrative-group
- show mpls rsvp counters
- show mpls rsvp neighbor
- show mpls rsvp session
- show mpls rsvp
- shutdown (MPLS RSVP)
- srlg
- timer recovery
- timer restart
- traffic-engineering srlg

RSVP-TE LER Commands

- administrative-group
- alias endpoint
- bandwidth
- color
- cspf delay
- cspf ecmp tie-break
- destination ip
- fast-reroute mode (RSVP tunnel)
- fast-reroute mode
- hop (dynamic path)

-
- hop (explicit path)
 - igp shortcut
 - local-interface
 - lsp self-ping
 - metric
 - optimization interval
 - path (path specification)
 - path (RSVP tunnel)
 - priority
 - refresh rsvp tunnel optimization
 - router traffic-engineering – not an RSVP command
 - rsvp
 - show traffic-engineering cspf path
 - show traffic-engineering database
 - show traffic-engineering rsvp tunnel history
 - show traffic-engineering rsvp tunnel lsp
 - show traffic-engineering rsvp tunnel name
 - show traffic-engineering rsvp tunnel sub-tunnel summary
 - show traffic-engineering rsvp tunnel summary
 - show traffic-engineering rsvp tunnel
 - show traffic-engineering rsvp
 - shutdown (MPLS RSVP)
 - shutdown (tunnel)
 - split-tunnel
 - srlg
 - traffic-engineering srlg
 - tunneling ldp
 - tunnel

20.4.1 administrative-group

The **administrative-group** command specifies the inclusion or exclusion of links that are part of an administrative group. The administrative group IDs are global and the specification contains lists and ranges of admin groups to include or exclude.

Every chosen link for a dynamic path must be in all of the admin groups specified in the **include all** range or must be in one of the admin groups specified in the **include any** range. A chosen link must not be in the **exclude** range. The administrative group range is 0 to 511.

Administrative groups can be specified using a name as an alias mapped to a numerical value. The mapping can be configured under the global Traffic-Engineering (TE) mode. For more information ,refer to the [IS-IS Traffic-Engineering TOI](#).

Command Mode

Traffic Engineering RSVP Tunnel Configuration

Command Syntax

```
administrative-group [ include any <RANGE> ] | [include all <RANGE>] | [exclude <RANGE>] with <RANGE> being: ( <0x0-0xFFFFFFFF> | <0-511> | <0-511>-<0-511> | WORD )
default administrative-group
no administrative-group
```

Parameters

exclude - Excludes the specified administrative group identified by either a group name or number.

include all - Includes the specified administrative groups identified by either a group name or number.

include any - Includes any of the specified range of administrative groups identified by either a group name or number.

Example

The following example states the path must include links from administrative group 1 and any link from an administrative group within groups 2, 3, or 4. The path must exclude links from administrative groups 7 and 9.

```
switch(config-te-rsvp-path-dyn-MyPath)# administrative-group include all 1
    include any 2-4 exclude 7,9
```

20.4.2 alias endpoint

The **alias endpoint** command configures a tunnel endpoint alias for both IPv4 and IPv6 endpoints and allows the additional next-hops to resolve using the existing tunnel. Use this command in the Router Traffic Engineering RSVP Tunnel Configuration Mode. Configure a maximum of 15 alias endpoints per tunnel.

Command Mode

Traffic Engineering RSVP Tunnel Configuration Mode

Command Syntax

```
alias endpoint [ ipv4_address | ipv6_address ]
no alias endpoint
default alias endpoint
```

Parameters

- **alias endpoint** - Specify adding a tunnel endpoint.
- ***ipv4_address*** - Specify an IPv4 address in the format A.B.C.D.
- ***ipv6_address*** - Specify an IPv4 address in the format A:B:C:D:E:F:G:H.

Example

Use the following commands to enter the Router Traffic Engineering RSVP Tunnel Configuration Mode, and add an alias endpoint, 192.168.11.5 to the existing *MyTunnel* configuration:

```
switch(config)# router traffic-engineering
switch(config-te)# rsvp
switch(config-te-rsvp)# tunnel MyTunnel
switch(config-te-rsvp-tunnel-MyTunnel)# alias endpoint 192.168.11.5
switch(config-te-rsvp-tunnel-MyTunnel) #
```

20.4.3 authentication index

The **authentication index** command configures the MPLS RSVP cryptographic authentication password globally for outgoing messages to the specified neighbor. Note that per-neighbor authentication takes precedence over global authentication.

The command **authentication index index_num active** is used to set the active password which is used when sending a message. The command **authentication index index_num password** is used to create the password with a given index. All configured passwords are used to authenticate incoming messages.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
authentication index <num> password<WORD>
[no|default] authentication index <num> password <WORD> password
[no|default] authentication index <num> password<WORD> active
```

Parameters

<num> index number chosen as the password for cryptographic authentication for messages sent to the specified neighbor.

<WORD> can be a plaintext password or a number that specifies the obfuscation method followed by the obfuscated password.

Example

The following commands globally enable cryptographic authentication (*RFC 2747*) for MPLS RSVP messages sent from the switch and establish the authentication index 755 and the password s3cr3t for outgoing messages:

```
switch(config)#mpls rsvp
switch(config-mpls-rsvp)# authentication type md5
switch(config-mpls-rsvp)# authentication index 755 password s3cr3t
switch(config-mpls-rsvp)# authentication index 755 active
```

20.4.4 authentication sequence-number window

The **authentication sequence-number window** command configures the size of the sequence number reorder window for incoming MPLS RSVP messages. Increasing the size of the window allows RSVP to accommodate a larger number of out-of-order packets. A value of N means that a packet is accepted if all previously received packets with a higher sequence number are within the preceding N-1 packets. The default value is 5. A value of 1 effectively turns off support for packet reordering.

Note: This command only has an effect if the authentication type is not none.

The **no authentication sequence-number window** and **default authentication sequence-number window** commands reset the size of the window to 5.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
authentication sequence-number window size_num  
no authentication sequence-number window  
default authentication sequence-number window
```

Parameters

- **size_num** - Sequence-number window size. Values range from 1-255. The default value is 5. A value of 1 disables packet reordering.

Example

The following commands set the sequence-number window to 50:

```
switch(config)#mpls rsvp  
switch(config-mpls-rsvp)# authentication sequence-number window 50  
switch(config-mpls-rsvp)#{
```

20.4.5 authentication type

The **authentication type** command configures the MPLS RSVP cryptographic authentication type globally. Setting the type to **md5** enables cryptographic authentication (*RFC 2747*) for MPLS RSVP messages sent from the switch. Setting the type to **none** disables authentication globally. Note that per-neighbor authentication settings takes precedence over global settings.

The **no authentication type** and **default authentication type** commands disable authentication. Cryptographic authentication is disabled by default. These commands are functionally the same as **authentication type none**.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
authentication type {md5 | none}
no authentication type {md5 | none}
default authentication type {md5 | none}
```

Parameters

- md5** = enables MPLS RSVP cryptographic authentication (*RFC 2747*) for the specified neighbor. A password for outgoing messages must also be configured using the **authentication index** command.
- none** - disables MPLS RSVP cryptographic authentication for messages sent to the specified neighbor.

Examples

- The following commands globally enable cryptographic authentication (*RFC 2747*) for MPLS RSVP messages sent from the switch and establish index 755 as the password for outgoing messages:

```
switch(config) #mpls rsvp
switch(config-mpls-rsvp) # authentication type md5
switch(config-mpls-rsvp) # authentication index 755 password s3cr3t
switch(config-mpls-rsvp) # authentication index 755 active
```

- The following commands disable cryptographic authentication globally:

```
switch(config) #mpls rsvp
switch(config-mpls-rsvp) # authentication type none
switch(config-mpls-rsvp) #
```

20.4.6 bandwidth

The **bandwidth** command configures the reserve bandwidth within the tunnel. The bandwidth can be set explicitly by setting a bandwidth value and the unit. When a bandwidth value of **0** is entered no bandwidth reservation is signalled. An alternative to explicit bandwidth configuration is to use the **autobandwidth** feature which specifies the minimum and maximum bandwidth to be used for the tunnel and otherwise adjusts bandwidth with an **adjustment period** based on the observed traffic going over the tunnel. The adjustment period is an optional parameter measured in seconds. The default adjustment period is 0 - a special value meaning that the algorithm decides when to adjust bandwidth based on statistical measurements (the actual adjustment cannot happen more frequently than the sampling, which occurs every 30 seconds).

Command Mode

Traffic Engineering RSVP Tunnel Configuration

Command Syntax

```
bandwidth 0-1000 (bps | kbps | mbps | gbps)  
bandwidth auto min (bps | kbps | mbps | gbps) 0-1000 max 0-1000 (bps | kbps | mbps | gbps) [  
adjustment-period seconds]  
bandwidth signaling [ disabled ]  
no bandwidth 0-1000 (bps | kbps | mbps | gbps)  
default bandwidth 0-1000 (bps | kbps | mbps | gbps)  
no bandwidth auto  
default bandwidth auto  
no bandwidth signaling  
default bandwidth signaling
```

Parameters

[bps | kbps | mbps | gbps] - Bandwidth values require the units of the value. The range of available units are bps, kbps, mbps, or gbps.

auto - Using the **auto** keyword configures autobandwidth within the configured minimum and maximum bandwidth and unit values. The tunnel adjusts the bandwidth based on the observed traffic going over the tunnel. This happens at adjustment interval, if configured. The default adjustment interval is 30 seconds, if no value is configured.

The **min** sets the minimum value and **max** sets the maximum value for the autobandwidth range. Each of the values require a unit to be selected.

The **signaling** keyword is used to enable signalling of the bandwidth reservation. A bandwidth of 0 returns signalling to the default of no signalling.

Example

- The following command explicitly configure the bandwidth of the tunnel to 10 mbps.

```
switch(config-te-rsvp-tunnel-myTunnel)# bandwidth 10 mbps
```

- The following command configures autobandwidth with a minimum of 1 mbps and maximum of 5 mbps. The bandwidth is set to be evaluated every 60 seconds.

```
switch(config-te-rsvp-tunnel-myTunnel)# bandwidth auto min 1 mbps max 5 mbps  
adjustment-period 60
```

20.4.7 clear mpls rsvp counters

The `clear mpls rsvp counters` command clears RSVP message counters. The `clear mpls rsvp counters (ip | ipv6) access-list` command clears the ACL counters.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
clear mpls rsvp counters  
clear mpls rsvp counters ( ip | ipv6 ) access-list
```

Parameters

- `ipv4` - Filter by IPv4.
- `ipv6` - Filter by IPv6.

Example

The following commands place the switch in Traffic Engineering RSVP configuration mode:

```
switch(config)#mpls rsvp  
switch(config-mpls-rsvp)# clear mpls rsvp counters
```

20.4.8 clear mpls rsvp session

The **clear mpls rsvp session** command can be used to clear RSVP sessions. Clearing a session will remove the current state for the LSPs and send the appropriate TEAR messages. This can be useful for cleaning up stale sessions, renegotiating a session immediately after a config change, or forcing a recreation of an LSP that could be in an error state.

Command Mode

EXEC

Command Syntax

```
clear mpls rsvp session ( <filters> | all ) [ detail ]
```

Parameter

With **<filters>** being a list of one or more of: (**destination <ipv4> | id <id>**) (**name <name> | lsp <lsp>** | **bypass**) (**role <role>**) (**state <state>**)

all - Clears all RSVP sessions.

bypass - Filter for bypass LSPs.

destination - Filter by destination address.

id - Filter by Session ID.

lsp - Filter by LSP number.

name - Filter by session name.

role - Filter by router role.

state - Filter by LSP state.

detail - Can be specified after **all** or any filters. When the command is run with **detail** the names of the sessions which are cleared are displayed, not just the count.

Examples

The following examples are on a switch with two RSVP sessions (**sessionA** and **sessionB**).

- This command clears all RSVP sessions on the switch.

```
switch# clear mpls rsvp session all
Cleared 2 sessions
```

- The **detail** keyword can be added to the end of the command to output the session name of all sessions being cleared.

```
switch# clear mpls rsvp session all detail
Clearing sessionA
Clearing sessionB
Cleared 2 sessions
```

- The **all** keyword can be replaced with filters to clear specific sessions. In the following example, the name **sessionA** filter is used to clear just sessionA.

```
switch# clear mpls rsvp session name sessionA detail
Clearing sessionA
Cleared 1 sessions
```

- The following is a list of the supported filters for the **clear** command. Some filters can be combined in a single command. For example, both the **bypass** and **state up** filters can be used in the same command to clear all bypass sessions which are in the up state.

```
switch# clear mpls rsvp session ?
      all          Clear all RSVP sessions
      bypass       Filter for bypass LSPs
      destination  Filter by destination address
      id           Filter by Session ID
      lsp          Filter by LSP#
      name         Filter by session name
      role         Filter by router role
      state        Filter by LSP state
```

20.4.9 color

The **color** command assigns a color to a tunnel to publish the tunnel to the **system-colored-rib**, to help steer traffic into the tunnel.

Command Mode

Traffic Engineering RSVP Tunnel Configuration

Command Syntax

color (<color value> | disabled)

default color - would inherit the color from the profile if one is configured

no color

color disabled - explicitly disables the color configuration irrespective of a profile being configured

Parameters

<color value> - numerical value in the range of 0 - 4292967295.

disable - disable the color attribute.

Example

The following example assigns color 60 to the MyTunnel:

```
switch(config-te-rsvp-tunnel-MyTunnel)# color 60
```

20.4.10 cspf delay

RSVP-TE uses CSPF to compute the FRR backup path. CSPF can be throttled to avoid frequent path changes when frequent network events occur. The **cspf delay** command configures the frequency of CSPF running after a network event by specifying the initial wait interval, back-off interval, and maximum wait interval for CSPF. The **no** form of the command removes the CSPF delay. The **default cspf delay** values are 100 for initial wait interval, 200 for back-off interval, and 1000 for maximum wait interval.

Command Mode

Router traffic engineering mode

Command Syntax

```
cspf delay [initial n back-off n] max n  
no cspf delay  
default cspf delay
```

Parameters

- **initial** - Specify initial wait interval for CSPF.
 - *n* - Specify the time in milliseconds. **1-300000**.
 - **back-off** - Specify the back-off interval for CSPF.
 - *n* - Specify the time in milliseconds. **1-300000**.
- **max** - Specify the maximum wait interval for CSPF.
 - *n* - Specify the time in milliseconds. **1-300000**.

Example

The following commands configure an initial wait interval, back-off interval, and maximum wait interval of 200, 400, and 2000 milliseconds respectively for CSPF delay:

```
switch(config)#router traffic-engineering  
switch(config-te)#cspf delay initial 200 back-off 400 max 2000  
switch(config-te)#{
```

20.4.11 cspf ecmp tie-break

The **cspf ecmp tie-break** command disables bandwidth least-fill when the **random** option is selected, and enables bandwidth least-fill when **least-fill** is selected. Bandwidth least-fill is enabled by default.

The **no** and **default** forms of the command restore bandwidth least-fill.

Command Mode

Traffic Engineering RSVP Configuration

Command Syntax

```
cspf ecmp tie-break (least-fill|random)
```

```
no cspf ecmp tie-break
```

```
default cspf ecmp tie-break
```

Parameters

- **least-fill** - Enables bandwidth least-fill.
- **random** - Disables bandwidth least-fill. Least-fill is enabled by default.

Example

- The following command disables bandwidth least-fill on the switch:

```
switch(config-te-rsvp) #cspf ecmp tie-break random  
switch(config-te-rsvp) #
```

20.4.12 destination ip

Each tunnel requires a destination IP to function. The **destination ip** command assigns a destination IP to the command-mode tunnel. For P2MP, this can be set multiple times, one for each of the multicast destinations.

Command Mode

Traffic Engineering RSVP Tunnel Configuration

Command Syntax

```
destination ip IP_address
```

```
no destination ip
```

```
default destination ip
```

Parameters

IP_address - The destination IPv4 address is required for the tunnel.

Example

The following command assigns destination IP 10.2.2.2 to the tunnel named MyTunnel:

```
switch(config-te-rsvp-tunnel-MyTunnel)# destination ip 10.2.2.2
```

20.4.13 fast-reroute bypass tunnel optimization interval

The **fast-reroute bypass tunnel optimization interval** command configures the interval at which paths used for bypass tunnels are re-optimized. Paths are re-optimized every 30 seconds by default.

The **no fast-reroute bypass tunnel optimization interval** and **default fast-reroute bypass tunnel optimization interval** commands return the optimization interval to the default value of 30 seconds.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
fast-reroute bypass tunnel optimization interval <number of seconds> seconds  
no fast-reroute bypass tunnel optimization interval  
default fast-reroute bypass tunnel optimization interval
```

Parameters

- **seconds** - The time between re-optimizations of bypass tunnel paths in seconds. The values range from 1 to 65535. Default is 30.

Example

The following commands set the bypass tunnel optimization interval to 45 seconds:

```
switch(config)# mpls rsvp  
switch(config-mpls-rsvp)# fast-reroute bypass tunnel optimization interval 45  
    seconds  
switch(config-mpls-rsvp) #
```

20.4.14 fast-reroute mode (RSVP tunnel)

The **fast-reroute mode** command by default, RSVP tunnels inherit fast-reroute settings from the global RSVP configuration. The fast-reroute mode can also be configured for a specific RSVP tunnel by issuing the command in Traffic Engineering RSVP Tunnel configuration mode. Note that this only modifies the type of protection requested by the tunnel. If the requested protection is not enabled by the global RSVP configuration, it may not be provided to the tunnel.

The **link-protection** option protects against failure of the next link, the **node-protection** option protects against failure of the next node, and the **none** option disables the feature.

The default is **no fast-reroute mode** which means that the inherit fast-reroute settings from the global RSVP configuration.

Command Mode

Traffic Engineering RSVP Tunnel Configuration

Command Syntax

```
fast-reroute mode { link-protection | node-protection | none }  
no fast-reroute mode  
default fast-reroute mode
```

Parameters

fast-reroute mode link-protection - Protect against failure of the next link.

fast-reroute mode node-protection - Protect against failure of the next node.

fast-reroute mode none - Disable fast reroute.

Example

- The following command enables fast reroute (FRR) link protection:

```
switch(config-te-rsvp-tunnel-MyTunnel)# fast-reroute mode link-protection
```

- The following command enables fast reroute (FRR) node protection:

```
switch(config-te-rsvp-tunnel-MyTunnel)# fast-reroute mode node-protection
```

- The following command disables FRR:

```
switch(config-te-rsvp-tunnel-MyTunnel)# fast-reroute mode none
```

20.4.15 fast-reroute mode

The **fast-reroute mode** command configures fast-reroute (FRR) (RFC 4090). The **link-protection** option protects against failure of the next link, the **node-protection** option protects against failure of the next node, and the **none** option disables the feature. Fast reroute is disabled by default.

On the headend, this knob acts as the global configuration which determines the type of protection requested by any LSPs originating there. This is superseded if the tunnels have a fast-reroute mode specified in the tunnel configuration (see [fast-reroute mode \(RSVP tunnel\)](#)) or in an associated profile.

On transit and headend, it also determines which type of bypass tunnels will be created at that node.

If node-protection is configured and requested by the LSP, then both node and link protection bypass tunnels will be created, with the node bypass being preferred if it's available.

If link-protection is configured or requested by the LSP, then only link-protection bypasses are created and used.

If the FRR mode is set to none or not requested at all by the LSP, then no bypass tunnels are created.

The **no** and **default** versions of the command disable fast reroute.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
fast-reroute mode (link-protection | node-protection | none)
```

```
no fast-reroute mode
```

```
default fast-reroute mode
```

Parameters

- **link-protection** - Protects against failure of the next link.
- **node-protection** - Protects against failure of the next node.
- **none** - Disables fast reroute.

Examples

- The following command enables fast reroute (FRR) link protection/NHOP (RFC 4090):

```
switch(config-mpls-rsvp)# fast-reroute mode link-protection
```

- The following command enables fast reroute (FRR) node protection/NNHOP (RFC 4090):

```
switch(config-mpls-rsvp)# fast-reroute mode node-protection
```

- The following command disables FRR:

```
switch(config-mpls-rsvp)# fast-reroute mode none
```

20.4.16 fast-reroute reversion

You can change the revertive behavior of the FRR from the **global** revertive mode to the **local** revertive mode. In the **global** revertive mode, an LSR re-routed over a bypass tunnel because the downstream link became unavailable keeps using the bypass tunnel after the link recovers. This expects the headend router to set up a new LSP upon notification that a link became unavailable. In the **local** revertive mode, the LSR switches back to using the primary link after recovery.

The default for reversion is **global**.

Command Mode

MPLS RSVP Configuration

Command syntax

```
fast-reroute reversion (global | local)
default fast-reroute reversion
no fast-reroute reversion
```

Parameters

- **global** - Global revertive mode.
- **local** - Local revertive mode.

Examples

- Set the fast-reroute reversion to local:

```
switch(config-mpls-rsvp)# fast-reroute reversion local
```

- The default for reversion is **global**.

```
switch(config-mpls-rsvp)# fast-reroute reversion global
```

20.4.17 graceful-restart role

The **graceful-restart role** command enables a graceful-restart role for RSVP (helper or speaker) and enters the configuration mode for that role. Graceful restart is disabled by default, and requires hello messages to be enabled.

The **no graceful-restart role** and **default graceful-restart role** commands disable the feature.

The helper mode is enabled under the RSVP configuration mode, **graceful-restart role helper**.

The maximum accepted restart time value is configurable under the RSVP Graceful Restart helper configuration mode, **timer restart maximum <t> seconds**.

The maximum accepted recovery time value is configurable under the RSVP Graceful Restart helper configuration mode, **timer recovery maximum <t> seconds**.

The speaker mode is enabled under the RSVP configuration mode, **graceful-restart role speaker**.

The restart time value is configurable under the RSVP Graceful Restart speaker configuration mode, **graceful-restart role speaker**.

The recovery time value is configurable under the RSVP Graceful Restart speaker configuration mode. **timer recovery <t> seconds**.

Command Mode

MPLS RSVP Configuration Mode

Command Syntax

```
graceful-restart role (helper | speaker)
```

```
no graceful-restart role (helper | speaker)
```

```
default graceful-restart role (helper | speaker)
```

timer restart maximum <t> seconds - The maximum accepted restart time value is configurable under helper configuration mode.

```
default timer restart maximum
```

```
no timer restart maximum
```

timer recovery maximum <t> seconds - The maximum accepted recovery time value, configured under helper configuration mode.

```
default timer recovery maximum
```

```
no timer recovery maximum
```

timer restart <t> seconds - The restart time value is configurable under the speaker configuration mode.

```
default timer restart
```

```
no timer restart
```

timer recovery <t> seconds - The recovery time value is configurable under the speaker configuration mode.

```
default timer recovery
```

```
no timer recovery
```

Parameters

- **helper** - Enables graceful restart in the helper role (assists with RSVP neighbor restarts) and enters Graceful Restart Helper configuration mode.
- **speaker** - Enables graceful restart in the speaker role (allows the local node to restart gracefully) and enters Graceful Restart Speaker configuration mode.

Example

The following commands enable graceful restart in the helper role and enter the configuration mode for that role:

```
switch(config)#mpls rsvp
switch(config-mpls-rsvp)#graceful-restart role helper
switch(config-mpls-rsvp-gr-helper) #
```

20.4.18 hello interval

The **hello interval** command sets the time between the hello packets. The **no** form of the command explicitly disables the Hello messages, while the **default** form of the command resets to the default setting of 10 seconds with a multiplier of 4.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
hello interval <sec>multiplier <num>
no hello interval
default hello interval
```

Parameters

- **interval sec** - The interval in units of seconds.
 - **multiplier num** - The value that is multiplied by the interval value.

Examples

- In this example, EOS sends hello messages to all known neighbors every **10** seconds. If the switch does not receive hello responses from a neighbor for $4 \times 10 = 40$ seconds, the switch loses communication and the neighbor resets.

```
switch(config-mpls-rsvp)# hello interval 10 multiplier 4
```

- In this example, the default of **10** seconds with multiplier **4** resets.

```
switch(config-mpls-rsvp)# default hello interval
```

- In this example, explicitly disable the Hello messages.

```
switch(config-mpls-rsvp)# no hello interval
```

20.4.19 hardware next-hop fast-failover

The **hardware next-hop fast-failover** command enables hardware-accelerated next-hop failover on the switch. This should be enabled in every case where FRR is desired, especially for sub-50ms in the case of link protection and sub-150ms in the case of node protection.

It is disabled by default. Bypass tunnels can still be created even without this knob and FRR will still work on the software side, but on the hardware this is necessary for fast convergence.

The **no** and **default** forms of the command disable hardware-accelerated next-hop failover and fast-reroute bypass tunnels.

Command Mode

Router General Configuration

Command Syntax

```
hardware next-hop fast-failover  
no hardware next-hop fast-failover  
default hardware next-hop fast-failover
```

Example

The following commands enable hardware-accelerated next-hop failover on the switch:

```
switch(config) #router general  
switch(config-router-general) #hardware next-hop fast-failover  
switch(config-router-general) #
```

20.4.20 hello-redundancy

The **hello-redundancy** command is suggested for Hello Redundancy when used with LDP over RSVP. Both peers require the configuration.

The neighbor hello-redundancy command configures Hello Redundancy on all platforms under the LDP configuration mode. Hello Redundancy means if a Link Hello Adjacency is lost it will not drop the sessions right away, but will continue to maintain a Targeted Hello adjacency for up to the configured time. Then, if Link Hello adjacency is NOT restored within the duration, it will drop the Targeted Hello adjacency and the session associated with it. The timeout can be configured using the duration option of the command. An infinite value for the duration disables the timeout.

Note: This configuration may not be required because the targeted adjacency will be established automatically by both peers based on the RSVP tunnel configuration.

Command Mode

MPLS-LDP Configuration

Command Syntax

```
neighbor hello-redundancy [duration seconds]
default neighbor hello-redundancy
no neighbor hello-redundancy
```

Parameter

Examples

These commands enable Targeted Hello redundancy with a duration of 300 seconds.

```
switch(config-mpls-ldp)# neighbor hello-redundancy
switch(config-mpls-ldp)# neighbor hello-redundancy duration 300
```

Use either of the following commands to disable Hello Redundancy.

```
switch(config-mpls-ldp)# neighbor hello-redundancy none
switch(config-mpls-ldp)# default neighbor hello-redundancy
```

20.4.21 hitless-restart

The **hitless-restart** command enables RSVP hitless restart. Hitless restart allows RSVP agents to restart without interrupting data-plane traffic. When hitless restart is enabled, the switch observes a recovery period after RSVP restarts. The switch preserves existing installed RSVP states until they are refreshed by neighbors. If RSVP states have not been refreshed before the expiration of the recovery period, they are cleared. The recovery period is 90 seconds by default, but can be configured using the **timer recovery** command. Hitless restart is disabled by default.

The **no hitless-restart** and **default hitless-restart** commands disable hitless restart.

The recovery time value **timer recovery <t> seconds** is configurable under the **hitless-restart** mode. .

The maximum accepted recovery time value **timer recovery maximum <t> seconds** is configurable under the **hitless-restart** mode, .

Command Mode

MPLS RSVP Configuration

Command Syntax

```
hitless-restart
no hitless-restart
default hitless-restart
```

timer recovery maximum <t> seconds - The maximum accepted recovery time value, configured under **hitless-restart** configuration mode.

```
default timer recovery maximum
```

```
no timer recovery maximum
```

timer recovery <t> seconds - The recovery time value is configurable under the **hitless-restart** configuration mode.

```
default timer recovery
```

```
no timer recovery
```

Parameters

Example

The following command enables RSVP hitless restart:

```
switch(config-mpls-rsvp)#hitless-restart
switch(config-mpls-rsvp)#{
```

20.4.22 hop (dynamic path)

The **hop** command adds a hop to the configuration-mode dynamic path. If entered without options, it is configured as a strict hop by default. A strict hop places the specified hop after the the previously specified hop. The **before** and **after** options can be used to insert the specified hop in relation to another hop in an existing path.

The **no** and **default** forms of the command remove

Command Mode

Traffic Engineering RSVP Explicit Path Configuration

Command Syntax

```
hop <IPv4_address> [ [exclude] | [loose] [ [before <IPv4_address> | after <IPv4_address>] ] ]
```

default hop <IPv4_address> - If no address is supplied then all hops are removed.

no hop [<IPv4_address>] - If no address is supplied then all hops are removed.

Parameters

- **exclude** - Specifies that CSPF must not choose the specified address on the path.
- **loose** - Defines the hop as a loose hop, which allows other hops to be filled by the CSPF procedure.
- **before** - Specifies the hop before which this hop will be placed.
- **after** - Specifies the hop after which this hop will be placed.

Example

- The following example excludes 10.0.56.6 from being used as a hop.

```
switch(config-te-rsvp-path-dyn-MyPath) # hop 10.0.56.6 exclude
```

- The following example configures 10.0.56.6 as the hop. Hop 10.0.45.5 uses the loose keyword, which allow other hops to be filled in before it. Hop 10.0.12.2 uses the before keyword to placed it before hop 10.0.23.3.

```
switch(config-te-rsvp-path-dyn-MyPath) # hop 10.0.23.3
switch(config-te-rsvp-path-dyn-MyPath) # hop 10.0.45.5 loose
switch(config-te-rsvp-path-dyn-MyPath) # hop 10.0.12.2 before 10.0.23.3
```

20.4.23 hop (explicit path)

The **hop** command adds a hop to the configuration-mode explicit path. If entered without options, the command places the specified hop in the order listed. The **before** and **after** options can be used to insert the specified hop in relation to another hop in an existing path.

Command Mode

Traffic Engineering RSVP Explicit Path Configuration

Command Syntax

```
hop <IPv4_address> [before IPv4_address | after <IPv4_address>]
```

default hop [<IPv4_address>] - If no address is supplied then all hops are removed.

no hop [<IPv4_address>] - If no address is supplied then all hops are removed.

Parameters

- **before** - Specifies the hop before which this hop will be placed.
- **after** - Specifies the hop after which this hop will be placed.
- **no** - Removes the specified hop.

Example

- The following commands create hop 10.0.12.2 and then places hop 10.0.34.4 after it.

```
switch(config-te-rsvp)# path MyPath explicit
switch(config-te-rsvp-path-expl-MyPath)# hop 10.0.12.2
switch(config-te-rsvp-path-expl-MyPath)# hop 10.0.34.4
```

- The following example places hop 10.0.23.3 before hop 10.0.34.4 and hop 10.0.45.5 is placed after hop 10.0.34.4.

```
switch(config-te-rsvp-path-expl-MyPath)# hop 10.0.23.3 before 10.0.34.4
switch(config-te-rsvp-path-expl-MyPath)# hop 10.0.45.5 after 10.0.34.4
```

20.4.24 label local-termination

The **label local-termination** command enables an egress LSR to advertise an IPv4 explicit-null label (Label 0) to its upstream router by using the **explicit-null** option.

The **no label local-termination** or **default label local-termination** or **label local-termination implicit-null** commands can be used to return the switch to the default state of advertising implicit-null labels (Label 3).

Note: When another label (e.g., VPN) is present, only switches that support multiple label termination can add an explicit-null label. These switches include the 7800R3, 7500R3 and 7280R3.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
label local-termination (explicit-null | implicit-null)
no label local-termination
default label local-termination
```

Parameters

- **explicit-null** - Advertises an explicit-null label to upstream RSVP router.
- **implicit-null** - Advertises an implicit-null label. This is the default.

Example

The following command configures the switch to advertise an explicit null label to its upstream RSVP router:

```
switch(config-mpls-rsvp)#label local-termination explicit-null
switch(config-mpls-rsvp) #
```

20.4.25 **igp shortcut**

The **igp shortcut** command is used to specify whether a RSVP tunnel should participate in Interior Gateway Protocol (IGP) shortcuts.

Command Mode

Traffic Engineering RSVP Tunnel Configuration

Command Syntax

```
igp shortcut  
default igp shortcut  
no igp shortcut
```

Parameters

disabled - disables the **igp shortcut** command.

Example

The following example configures the tunnel named MyTunnel to participate in IGP shortcuts.

```
switch(config-te-rsvp-tunnel-MyTunnel)# igp shortcut
```

20.4.26 local-interface

The **local-interface** command specifies a local interface from which to derive the source IP address for RSVP-TE tunnels.

Command Mode

Traffic Engineering RSVP Configuration

Command Syntax

```
local-interface int_type int_num
no local-interface
default local-interface
```

Parameters

- ***int_type*** Interface type for the local interface. Values include **Ethernet**, **Fabric**, **Loopback**, **Management**, **Port-Channel**, **Recirc-Channel**, **Tunnel**, **Vlan**, and **Vxlan**.
- ***int_num*** Interface number for the local interface.

Example

The following command specifies loopback interface 0 as the local interface:

```
switch(config-te-rsvp)#local-interface Loopback 0
switch(config-te-rsvp) #
```

20.4.27 lsp self-ping

The **lsp self-ping** command enables LSP self-ping (RFC 7746). When enabled, all new LSPs created by RSVP-TE LER tunnels will perform self-ping. LSP self-ping verifies end-to-end establishment of the LSP by sending a self-ping message through the LSP before sending regular traffic. When LSP self-ping is enabled, an LSP created by an RSVP-TE tunnel will only be considered up and ready to carry traffic when a self-ping message successfully returns to the head end. LSP self-ping is disabled by default.

The **no** and **default** forms of the command disable LSP self-ping.

Command Mode

Global Configuration

Command Syntax

```
lsp self-ping  
default lsp self-ping  
no lsp self-ping
```

Parameters

Example

The following command enables LSP self-ping:

```
switch(config-te-rsvp)#lsp self-ping  
switch(config-te-rsvp) #
```

20.4.28 metric

The **metric** command configures a per RSVP tunnel metric to allow specific tunnels to a tunnel endpoint take precedence over other tunnels to the same tunnel endpoint when forming ECMP. The tunnel **metric** publishes to the tunnel RIB for BGP cost calculations.

The tunnel metric can also dynamically track the IGP SPF metric for the tunnel destination IP regardless of the changes in the Constraint-based Shortest Path First (CSPF) path to the destination.

Command Mode

Router Traffic Engineering RSVP Tunnel Configuration Mode

Command Syntax

```
metric ( igrp | metric_value)  
default metric  
no metric
```

Parameters

- **metric** - Specify a metric for the tunnel.
 - **igrp** - Specify to use the IPG SPF metric.
 - **metric_value** - Specify a static metric value between 0 and 4294967295.

Example

Use the following commands to enter the Router Traffic Engineering RSVP Tunnel Configuration Mode, and add a static metric, *10* to the existing *MyTunnel* configuration:

```
switch(config)# router traffic-engineering  
switch(config-te)# rsvp  
switch(config-te-rsvp)# tunnel MyTunnel  
switch(config-te-rsvp-tunnel-MyTunnel)# metric 10  
switch(config-te-rsvp-tunnel-MyTunnel) #
```

Use the following commands to enter the Router Traffic Engineering RSVP Tunnel Configuration Mode, and add the IGP SPF metric, *igp*, to the existing *MyTunnel* configuration:

```
switch(config)# router traffic-engineering  
switch(config-te)# rsvp  
switch(config-te-rsvp)# tunnel MyTunnel  
switch(config-te-rsvp-tunnel-MyTunnel)# metric igrp  
switch(config-te-rsvp-tunnel-MyTunnel) #
```

20.4.29 mpls rsvp

The `mpls rsvp` command places the switch in MPLS RSVP configuration mode.

Command Mode

Global Configuration

Command Syntax

```
mpls rsvp
```

`default mpls rsvp` - Will wipe the configuration in the mode and disable RSVP.

`no mpls rsvp` - Will wipe the configuration in the mode and disable RSVP.

Commands Available in MPLS RSVP Configuration Mode

- authentication index
- authentication sequence-number window
- authentication type
- fast-reroute bypass tunnel optimization interval
- fast-reroute mode
- fast-reroute reversion
- graceful-restart role
- hello interval
- hitless-restart
- ip access-group
- ipv6 access-group
- label local-termination
- mtu signaling
- neighbor authentication index
- neighbor authentication type
- p2mp
- preemption method
- refresh interval
- refresh method
- shutdown (MPLS RSVP)
- srlg

Example

The following command places the switch in MPLS RSVP configuration mode:

```
switch(config) # mpls rsvp
switch(config-mpls-rsvp) #
```

20.4.30 mtu signaling

The **mtu signaling** command configures RSVP to enable MTU discovery. MTU signaling is disabled by default. The MTU is discovered with the AdSpec object in the Path message, which contains the minimum MTU seen in the path so-far, and is then reported back in the Resv message. If the config knob is not set on a transit node, then the MTU in the AdSpec is not updated on the node (essentially ignoring the node for MTU discovery). If it is not set on the ingress node, then MTU discovery is not done for any LSPs originating at that node.

The **no mtu signaling**, **default mtu signaling**, and **default mtu signaling** commands disable MTU signaling, preventing the updating of composed MTUs.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
mtu signaling  
no mtu signaling  
default mtu signaling
```

Example

The following command enables MTU signaling on the switch:

```
switch(config-mpls-rsvp)#mtu signaling  
switch(config-mpls-rsvp) #
```

20.4.31 neighbor authentication index

The **neighbor authentication index** command configures the MPLS RSVP cryptographic authentication password for outgoing messages to the specified neighbor. Per-neighbor authentication takes precedence over global authentication.

The **no neighbor authentication index** and **default neighbor authentication index** commands remove neighbor-specific authentication password configuration; the neighbor then inherits the global configuration.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
neighbor neighbor_address authentication index index_num active  
no neighbor neighbor_address authentication index index_num active  
default neighbor neighbor_address authentication index index_num active
```

Parameters

- ***neighbor_address*** - address of the MPLS RSVP neighbor.
- ***index_num*** - index number chosen as the password for cryptographic authentication for messages sent to the specified neighbor.

Examples

The following commands enable cryptographic authentication for the neighbor at 172.16.0.0 and establishes index 755 as the password for outgoing messages to that neighbor:

```
switch(config)#mpls rsvp  
switch(config-mpls-rsvp)# neighbor 172.16.0.0 authentication type md5  
switch(config-mpls-rsvp)# neighbor 172.16.0.0 authentication index 755 active  
switch(config-mpls-rsvp) #
```

20.4.32 neighbor authentication type

The **neighbor authentication type** command configures the MPLS RSVP cryptographic authentication type for the specified neighbor. Setting the type to **md5** enables cryptographic authentication (*RFC 2747*) for MPLS RSVP messages sent to the specified neighbor. Setting the type to **none** disables authentication for the neighbor. Note that per-neighbor authentication takes precedence over global authentication.

The **no neighbor authentication** and **default neighbor authentication** commands remove neighbor-specific authentication type configuration; the neighbor then inherits global configuration.

Command Mode

MPLS RSVP Configuration

Command Syntax

```
neighbor neighbor_address authentication type (md5 | none)
```

```
no neighbor neighbor_address authentication type
```

```
default neighbor neighbor_address authentication type
```

Parameters

- **neighbor_address** - address of the MPLS RSVP neighbor.
- **md5** - enables MPLS RSVP cryptographic authentication (*RFC 2747*) for the specified neighbor. A password for outgoing messages must also be configured using the **neighbor authentication index** command.
- **none** - disables MPLS RSVP cryptographic authentication for messages sent to the specified neighbor.

Examples

- The following commands enable cryptographic authentication for the neighbor at 172.16.0.0 and establishes index 755 as the password for outgoing messages to that neighbor:

```
switch(config)#mpls rsvp
switch(config-mpls-rsvp)# neighbor 172.16.0.0 authentication type md5
switch(config-mpls-rsvp)# neighbor 172.16.0.0 authentication index 755
  active
switch(config-mpls-rsvp) #
```

- The following commands disable cryptographic authentication for the neighbor at 172.16.0.0:

```
switch(config)#mpls rsvp
switch(config-mpls-rsvp)# neighbor 172.16.0.0 authentication type none
switch(config-mpls-rsvp) #
```

20.4.33 optimization interval

Periodic tunnel optimization can be configured globally or individually for a specific tunnel using the **optimization interval** command. This configuration is applied to all RSVP tunnels.

The optimization interval can also be configured on an individual tunnel by entering the command in tunnel sub-mode. The optimization interval configured in the tunnel sub-mode overrides the optimization interval configured globally.

Optimization can also be disabled on a specific tunnel or globally, which is the default.

Command Mode

Traffic Engineering RSVP Configuration

Traffic Engineering RSVP Tunnel Configuration

Command Syntax

```
optimization interval <numerical value> seconds
default optimization
no optimization
```

Parameters

numerical value - enter the optimization interval in seconds.

Example

- The following command configures all RSVP tunnels to be re-optimized every 3600 seconds:

```
switch(config-te-rsvp)#optimization interval 3600 seconds
```

- The following commands configured an optimization interval of 3600 seconds on the tunnel named myTunnel. This tunnel-specific configuration overrides the global optimization configuration.

```
switch(config-te-rsvp)#tunnel myTunnel
switch(config-te-rsvp-tunnel-myTunnel)#optimization interval 3600 seconds
```

- The following commands configure an optimization interval of 3600 seconds for all tunnels but disable automatic optimization on the tunnel named myTunnel:

```
switch(config-te-rsvp)#optimization interval 3600 seconds
switch(config-te-rsvp)#tunnel myTunnel
switch(config-te-rsvp-tunnel-myTunnel)#optimization disabled
switch(config-te-rsvp-tunnel-myTunnel) #
```

20.4.34 p2mp

From the **config-mpls-rsvp** configuration mode, the **p2mp** command places the switch in **mpls-rsvp-p2mp** configuration mode.

Command Mode

MPLS-RSVP Configuration Mode

Command Syntax

```
p2mp  
default p2mp  
no p2mp
```

Parameter

p2mp - Enables RSVP P2MP.

no p2mp - Disables RSVP P2MP.

default p2mp - Disables RSVP P2MP.

Examples

- RSVP P2MP signaling functionality is enabled using the **p2mp** command.

```
switch# config  
switch(config)# mpls rsvp  
switch(config-mpls-rsvp)# no shutdown  
switch(config-mpls-rsvp)# p2mp  
switch(config-mpls-rsvp-p2mp) #
```

- P2MP functionality is disabled by issuing the **disabled** command in the p2mp submode. This allows disabling RSVP P2MP without wiping any active configuration in the p2mp sub-mode.

```
switch(config-mpls-rsvp-p2mp)# disabled  
switch(config-mpls-rsvp-p2mp) #
```

- The **no p2mp** will both remove the p2mp sub-mode configuration and also disable RSVP P2MP.
- ```
switch(config-mpls-rsvp)# no p2mp
switch(config-mpls-rsvp) #
```
- The **exit** command will leave the sub-mode but will retain the configuration in it.

```
switch(config-mpls-rsvp-p2mp)# exit
switch(config-mpls-rsvp) #
```

### 20.4.35 path (path specification)

The **path** command in Traffic Engineering RSVP Tunnel P2P configuration mode specifies the configuration mode for the path. If the path does not already exist, it creates it. Path configuration modes are group-change modes: changes take effect only when exiting the mode. To exit the mode without saving changes, use the **abort** command.

The **no path** and **default path** commands delete the specified path.

**Note:** A path of a specific name can only be explicit or dynamic, and once a path is created its type cannot be changed. To change a named path from explicit to dynamic or vice versa, delete the path by using the **no** form of the command and create it again.

#### Command Mode

- Traffic Engineering RSVP Configuration

#### Command Syntax

**path spec\_name (dynamic | explicit)**

**no path spec\_name**

**default path spec\_name**

#### Parameters

- **spec\_name** - Specification name for the path.
- **dynamic** - Establishes a dynamic path.
- **explicit** - Establishes an explicit path.

#### Example

The following commands creates an explicit path named `spec1` for the tunnel `tunnel17` and enters the configuration mode for that path.

```
switch(config-te-rsvp) #tunnel tunnel17
switch(config-te-rsvp-tunnel-tunnel17) # path spec1
```

---

## 20.4.36 path (RSVP tunnel)

The **path** command in Traffic Engineering RSVP Tunnel configuration mode specifies a primary or secondary path along which the LSPs are established for the configuration-mode RSVP tunnel.

The **no** and **default** forms of the command remove the named path.

### Command Mode

Traffic Engineering RSVP Tunnel Configuration

### Command Syntax

```
path spec_name (secondary pre-signaled)
no path spec_name (secondary)
default path spec_name (secondary)
```

### Example

- The following commands create a path named **path6** for the tunnel named **tunnel13**:

```
switch(config-te-rsvp)#tunnel tunnel13
switch(config-te-rsvp-tunnel-tunnel13)#path path6
switch(config-te-rsvp-tunnel-tunnel13) #
```

- The following commands create a pre-signaled secondary path named **path7** for the tunnel named **tunnel13**:

```
switch(config-te-rsvp)#tunnel tunnel13
switch(config-te-rsvp-tunnel-tunnel13)#path path7 secondary pre-signaled
switch(config-te-rsvp-tunnel-tunnel13) #
```

## 20.4.37 ping mpls rsvp session

The **ping mpls rsvp session** command allows the user to check if the remote endpoint of an RSVP session is reachable through the LSP. Running ping on an RSVP LSP creates an LSP Ping Request packet with the label programmed by RSVP and that packet will follow the MPLS path until it reaches the end of the tunnel. If the node that receives this Request is the intended destination, it replies with an RSVP Ping Reply through normal IP routing. When the source receives the Reply it indicates that there are no apparent data plane failures and that the endpoint of that LSP is reachable.

### Command Mode

Privileged EXEC mode

### Command Syntax

```
ping mpls rsvp session ([id num [lsp lspd] | name word] [pad-reply] [repeat <num_repeat>]
[source (IPv4_address | IPv6_address)] [standard (arista|ietf)] | [tos (<tos_value> | dscp
<dscp_value>)] [traffic-class <traffic_class>] [interval <interval_value>]
```

### Parameters

- **id** - Specifies the session by ID.
  - **num** - RSVP session ID.
    - **lsp** - Specifies LSP. This parameter can only be specified with the id parameter.
    - **pad-reply** - Indicates that the reply should copy the pad TLV.
    - **repeat** - Specifies repeat count.
    - **source** - Specifies source address.
    - **standard** - Sets the standard to comply with.
    - **tos** - Specifies ToS value.
    - **traffic-class** - Specifies MPLS traffic class field.
    - **interval** - Specify interval between requests
    - **size** - Specify packet size in bytes
  - **name** - Specifies session by name.
    - **word** - RSVP session name.
      - **pad-reply** - Indicates that the reply should copy the pad TLV.
      - **repeat** - Specifies repeat count.
      - **source** - Specifies source address.
      - **standard** - Sets the standard to comply with.
      - **tos** - Specifies ToS value.
      - **traffic-class** - Specifies MPLS traffic class field.
      - **interval** - Specify interval between requests
      - **size** - Specify packet size in bytes

### Examples

- In the following example, the ping utility checks if the remote endpoint of an RSVP session is reachable through the LSP.

```
switch# ping mpls rsvp session id 1 lsp 1 repeat 3
LSP ping to RSVP session #1 LSP #1
 timeout is 5000ms, interval is 1000ms
 Via 10.0.12.2, Ethernet1, label 100000
 Reply from 10.0.34.4: seq=1, time=53.294ms, success: egress ok
 Via 10.0.12.2, Ethernet1, label 100000
 Reply from 10.0.34.4: seq=2, time=75.329ms, success: egress ok
 Via 10.0.12.2, Ethernet1, label 100000
 Reply from 10.0.34.4: seq=3, time=85.574ms, success: egress ok
```

```

--- RSVP target fec 0.4.4.4 : lsppping statistics ---
Via 10.0.12.2, Ethernet1, label 100000
 3 packets transmitted, 3 received, 0% packet loss, time 2272ms
 3 received from 10.0.34.4, rtt min/max/avg 53.294/85.574/71.399 ms

```

- For the **ping mpls rsvp session** command, the argument **Lsp** is optional. If unspecified, the utility pings all LSPs within that session.

```

switch# ping mpls rsvp session id 1 repeat 2
LSP ping to RSVP session #1
 timeout is 5000ms, interval is 1000ms
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
 Reply from 10.0.34.4: seq=1, time=60.28ms, success: egress ok
LSP 2
Via 10.0.12.2, Ethernet1, label 100002
 Reply from 10.0.34.4: seq=1, time=81.701ms, success: egress ok
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
 Reply from 10.0.34.4: seq=2, time=52.807ms, success: egress ok
LSP 2
Via 10.0.12.2, Ethernet1, label 100002
 Reply from 10.0.34.4: seq=2, time=62.814ms, success: egress ok

--- RSVP target fec 0.4.4.4 : lsppping statistics ---
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
 2 packets transmitted, 2 received, 0% packet loss, time 1262ms
 2 received from 10.0.34.4, rtt min/max/avg 52.807/60.280/56.544 ms

LSP 2
Via 10.0.12.2, Ethernet1, label 100002
 2 packets transmitted, 2 received, 0% packet loss, time 1262ms
 2 received from 10.0.34.4, rtt min/max/avg 62.814/81.701/72.257 ms

```

- In the following example, the session is specified by name and the utility pings all the LSPs within that session.

```

switch# ping mpls rsvp session name Session1to4 repeat 2
LSP ping to session Session1to4
 timeout is 5000ms, interval is 1000ms
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
 Reply from 10.0.34.4: seq=1, time=63.314ms, success: egress ok
LSP 2
Via 10.0.12.2, Ethernet1, label 100002
 Reply from 10.0.34.4: seq=1, time=75.639ms, success: egress ok
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
 Reply from 10.0.34.4: seq=2, time=60.875ms, success: egress ok
LSP 2
Via 10.0.12.2, Ethernet1, label 100002
 Reply from 10.0.34.4: seq=2, time=77.135ms, success: egress ok

--- RSVP target fec 0.4.4.4 : lsppping statistics ---
LSP 1
Via 10.0.12.2, Ethernet1, label 100000
 2 packets transmitted, 2 received, 0% packet loss, time 1262ms
 2 received from 10.0.34.4, rtt min/max/avg 60.875/63.314/62.094 ms

LSP 2
Via 10.0.12.2, Ethernet1, label 100002
 2 packets transmitted, 2 received, 0% packet loss, time 1262ms
 2 received from 10.0.34.4, rtt min/max/avg 75.639/77.135/76.387 ms

```

## 20.4.38 preemption method

The **preemption method** command enables deferred failure of RSVP-TE LSPs on link oversubscription. Hard preemption will result in the LSP being torn down without any delay. Use a preemption timer value to configure a delay, before tearing down an LSP due to losing its bandwidth reservation, on a transit router to support LSPs signaled with soft preemption enabled by the headend (*RFC 5712*).

The default preemption method is soft preemption with a timer value of 30 seconds.

### Command Mode

MPLS RSVP Configuration

### Command Syntax

```
preemption method (hard | soft) [timer <seconds>]
no preemption method
default preemption method
```

### Parameters

- **hard** - Hard preemption. The timer value is ignored.
- **soft** - Soft preemption.
  - **timer** - Time limit for LSP teardown. Only applies to soft-preemption. If the timer keyword is not used the default timer of 30 seconds is used.
    - **<seconds> 1-65535** - Timer value in units of seconds.

### Examples

- In this example, the preemption method is soft preemption with a timer value of **10** seconds.

```
switch(config-mpls-rsvp)# preemption method soft timer 10
```

- Setting the preemption method to hard preemption results in a timer value of **0** seconds and disables the feature.

```
switch(config-mpls-rsvp)# preemption method hard
```

---

## 20.4.39 priority

The **priority** command configures the tunnel priority. The **setup** keyword is used to set the priority of the setup. The **hold** keyword sets the priority of the tunnel hold. The priority value range is 0 (highest priority) to 7 (lowest priority). The **setup** priority can be used without a **hold** priority, but a **hold** priority requires a **setup** priority to be set.

When both **setup** and **hold** priorities are configured, the **hold** value should be a higher priority (lower value) than the **setup** priority to avoid cycles where an LSP is continuously established and immediately preempted.

### Command Mode

Traffic Engineering RSVP Tunnel Configuration

### Command Syntax

**priority 0-7**

**no priority** - Default setting and will inherit from profile. The default profile values are: priority setup 7 hold 0

**default priority**

### Parameters

- **setup** - requires a priority value **0-7**
- **hold** - requires a priority value **0-7**

### Example

The following example configures a **setup** priority 5 and a **hold** priority 3. The **hold** priority is a lower value, meaning it has a higher priority.

```
switch(config-te-rsvp-tunnel-myTunnel)# priority setup 5 hold 3
```

## 20.4.40 refresh interval

The **refresh interval** command configures the interval at which MPLS RSVP Path and Resv messages are sent to refresh the state. State is refreshed at a randomly selected interval between 0.5 and 1.5 times the configured value. The default value is 30 seconds.

The **no** and **default** versions of the command reset the refresh interval to 30 seconds.

### Command Mode

MPLS RSVP Configuration

### Command Syntax

**refresh interval *seconds***

**no refresh interval**

**default refresh interval**

### Parameters

**seconds** - Refresh interval in seconds. The actual refresh interval is randomly generated in the range of 0.5 to 1.5 times this value. Values range from 1 to 65535. Default value is 30.

### Example

The following command configures an interval of 100 seconds at which MPLS RSVP Path and Resv messages are sent to refresh the state:

```
switch(config-mpls-rsvp)#refresh interval 100
switch(config-mpls-rsvp)#{
```

---

## 20.4.41 refresh method

Using the **Srefresh method** command with the **bundled** keyword enables the Refresh Overhead Reduction that supports the sending of message IDs and refreshing state with refresh messages.

### Command Mode

MPLS RSVP Configuration

### Command Syntax

**Srefresh method [bundled | explicit ]**

**no Srefresh method** - More tokens allowed but ignored.

**default Srefresh method** - More tokens allowed but ignored.

### Parameters

- **bundled** - Refresh states using message identifiers lists. This is the default setting.
- **explicit** - Send each refresh message individually.

### Examples

- Use the **bundled** keyword to enable the Refresh Overhead Reduction.

```
switch(config-mpls-rsvp)# refresh method bundled
```

- To turn off refresh overhead reduction, use the **explicit** keyword.

```
switch(config-mpls-rsvp)# refresh method explicit
```

## 20.4.42 refresh rsvp tunnel optimization

When periodic tunnel optimization is not configured, tunnels will not re-optimize automatically, but they can be optimized on demand by using the **refresh rsvp tunnel optimization** command.

### Command Mode

Privileged Exec

### Command Syntax

```
refresh rsvp tunnel optimization (all | name tunnel_name [avoid ecmp hop ecmp_hops])
```

### Parameters

- **all** Optimizes all tunnels.
- **name *tunnel\_name*** Optimizes the named tunnel.
- **avoid ecmp hop *ecmp\_hops*** The on-demand optimization can also be used to move a tunnel between different equal-cost options. A set of links can be passed to CSPF to avoid while finding another equal-cost path. This operation works only on equal-cost paths and will not switch the tunnel to a less optimal path. The variable *ecmp\_hops* is a list of IP(v4) addresses.

### Example

- The following command optimizes the tunnel named myTunnel:

```
switch# refresh rsvp tunnel optimization name myTunnel
switch#
```

- The following command optimizes the tunnel named myTunnel and recomputes the tunnel path to avoid 198.51.100.17:

```
switch# refresh rsvp tunnel optimization name myTunnel avoid ecmp hop
198.51.100.17
switch#
```

- The following command performs optimization on all tunnels:

```
switch# refresh rsvp tunnel optimization all
switch#
```

---

## 20.4.43 router traffic-engineering – not an RSVP command

The `router traffic-engineering` command places the switch in Traffic Engineering configuration mode.

### Command Mode

Global Configuration

### Command Syntax

```
router traffic-engineering
```

### Parameters

#### Example

The following command places the switch in Traffic Engineering configuration mode:

```
switch(config) # router traffic-engineering
switch(config-te) #
```

## 20.4.44 rsvp

The **rsvp** command places the switch in Traffic Engineering RSVP configuration mode.

**Note:** Use caution when using the **no** and **default rsvp** versions of this command. The whole mode will be removed. Use with care.

### Command Mode

Traffic Engineering Configuration

### Command Syntax

```
rsvp
default rsvp
no rsvp
```

### Commands Available in RSVP Configuration Mode

- cspf ecmp tie-break
- local-interface Loopback
- lsp self-ping
- optimization interval <NumberofSeconds> seconds
- path <PathName> dynamic
- path <PathName> explicit
- show active
- tunnel <TunnelName>

### Example

The following commands place the switch in Traffic Engineering RSVP configuration mode:

```
switch(config) #router traffic-engineering
switch(config-te) #rsvp
switch(config-te-rsvp) #
```

---

## 20.4.45 rsvp bypass administrative-group

The **rsvp bypass administrative-group** command specifies administrative groups that must be included in, or excluded from, the links used for CSPF path computation. The restrictions specified for an interface apply to all LSPs that bypass that interface. This includes both link and node protection. A single command can incorporate ranges for include any, include all, and exclude.

The **no rsvp bypass administrative-group** and **default rsvp bypass administrative-group** commands remove bypass restrictions for the interface.

### Command Mode

Interface Configuration

### Command Syntax

```
rsvp bypass administrative-group [include any <RANGE>] | [include all <RANGE>] |
[exclude <RANGE>] with <RANGE> being: (<0x0-0xFFFFFFFF> | <0-511> | <0-511>-<0-511> | WORD)
no rsvp bypass administrative-group
default rsvp bypass administrative-group
```

### Parameters

**exclude** - Excludes the specified administrative group identified by either a group name or number.

**include all** - Includes the specified administrative groups identified by either a group name or number.

**include any** - Includes any of the specified range of administrative groups identified by either a group name or number.

### Example

The following commands specify that links used for CSPF path computation on Ethernet interface 1/1 must include all administrative groups in the range from 5 to 16 and any group from the range from 8 to 75, and must exclude groups 82, 93, 115 to 168, and 255:

```
switch(config)#interface ethernet 1/1
switch(config-if-Et1/1)#rsvp bypass administrative-group include all 5-16
 include any 8-75 exclude 82,93,115-168,255
switch(config-if-Et1/1) #
```

## 20.4.46 show mpls rsvp

Use the `show mpls rsvp` to display the overall state of the RSVP.

### Command Mode

EXEC

### Command Syntax

```
show mpls rsvp [bandwidth | counters | ((ip | ipv6) access-list (<name> | dynamic | summary)) | neighbor | session]
```

### Parameters

- **bandwidth** - Displays RSVP bandwidth information.
- **counters** - Displays RSVP message counters.
- **ip** - Displays details related to IPv4 ACLs.
- **ipv6** - Displays details related to IPv6 ACLs.
- **neighbor** - Displays RSVP neighbor information.
- **session** - Displays RSVP session information.

### Example

The following example display the overall state of the RSVP.

```
switch> show mpls rsvp
Administrative state: enabled
Operational state: up
Refresh interval: 30 seconds
Refresh reduction: enabled
Hello messages: enabled
 Hello interval: 10 seconds
 Hello multiplier: 4
Fast Re-Route: disabled
 Mode: none
 Hierarchical FECs: enabled
Cryptographic authentication: disabled
MTU signaling: disabled
Number of sessions: 1
 Ingress/Transit/Egress: 0/1/0
Number of LSPs: 1
 Operational: 1
 Ingress/Transit/Egress: 0/1/0
 Currently using bypass tunnels: 0
Number of bypass tunnels: 0
Number of neighbors: 2
Number of interfaces: 2
```

## 20.4.47 show mpls rsvp counters

Use the **show mpls rsvp counters** command to display RSVP message counters, per interface. The address family filter has to be specified first, if it is specified. Then the interface filter is specified, if it is specified. This cannot be done in the opposite order.

### Command Mode

EXEC

### Command Syntax

```
show mpls rsvp counters [ipv4 | ipv6] [interface [Ethernet |Fabric | Loopback | Management | Port-Channel | Switch | Tunnel | Vlan | Vxlan]]
```

### Parameters

**Note:** The available interface filters are dependent on the platform support. Available filters may be different than the following examples.

- **interface** Filter by interface.
  - **Ethernet** - Hardware Ethernet interface.
  - **Fabric** - Fabric interfaces.
  - **Loopback** - Hardware interface used for looping packets.
  - **Management** - Management interface.
  - **Port-Channel** - Lag interface.
  - **Switch** - Switch interface.
  - **Tunnel** - Tunnel interface.
  - **Vlan** - Logical interface into a VLAN.
  - **Vxlan** - VXLAN tunnel interface.
- **ipv4** - Filter by IPv4.
- **ipv6** - Filter by IPv6.

### Example

The following example displays RSVP message counters for each interface.

```
switch> show mpls rsvp counters
Received Messages:

Interface Path PathTear PathErr Resv ResvTear ResvErr Srefresh Other Errors
----- ---- ----- ----- ----- ----- ----- -----
Ethernet1 5 0 0 0 0 0 8 51 1
Ethernet2 0 0 0 14 0 0 0 0 0

Sent Messages:

Interface Path PathTear PathErr Resv ResvTear ResvErr Srefresh Other Errors
----- ---- ----- ----- ----- ----- ----- -----
Ethernet1 0 0 0 4 0 0 9 49 0
Ethernet2 13 0 0 0 0 0 0 4 0
```

## 20.4.48 show mpls rsvp neighbor

Use the **show mpls rsvp neighbor** command to display information about all RSVP neighbors, or for a specific neighbor.

### Command Mode

EXEC

### Command Syntax

```
show mpls rsvp neighbor [A.B.C.D | A:B:C:D:E:F:G:H | summary]
```

### Parameters

- **A.B.C.D** - IP (v4 or v6) address of neighbor.
- **A:B:C:D:E:F:G:H** - IP (v4 or v6) address of neighbor.
- **summary** - Displays summarized information.

### Examples

- Use the **show mpls rsvp neighbor** command to display information about all RSVP neighbors.

```
switch> show mpls rsvp neighbor
Neighbor 10.0.1.1
 Upstream for
 Session #1 LSP #1
 Downstream for
 Neighbor uptime: 00:01:24
 Authentication type: disabled
 Last hello received: 1 seconds ago
 Last hello sent: 1 seconds ago
 Bypass tunnel: not requested
Neighbor 10.0.2.2
 Upstream for
 Downstream for
 Session #1 LSP #1
 Neighbor uptime: 00:01:24
 Authentication type: disabled
 Last hello received: -
 Last hello sent: 31 seconds ago
 Bypass tunnel: not requested
```

- Use the **show mpls rsvp neighbor summary** command to display summarized information.

```
switch> show mpls rsvp neighbor summary
Neighbor Role Sessions LSPs
===== ====== ====== =====
10.0.1.1 Upstream 1 1
10.0.2.2 Downstream 1 1
```

## 20.4.49 show mpls rsvp session

The `show mpls rsvp session` command displays RSVP session information.

### Command Mode

EXEC

### Command Syntax

```
show mpls rsvp session (<filters> | all) [detail]
```

### Parameter

With `<filters>` being a list of one or more of: ( `destination <ipv4> | id <id>` ) ( `name <name> | lsp <lsp>` | `bypass` ) ( `role <role>` ) ( `state <state>` )

`all` - Clears all RSVP sessions.

`bypass` - Filter for bypass LSPs.

`destination` - Filter by destination address.

`id` - Filter by Session ID.

`lsp` - Filter by LSP number.

`name` - Filter by session name.

`role` - Filter by router role.

`state` - Filter by LSP state.

`detail` - Can be specified after `all` or any filters. When the command is run with `detail` the names of the sessions which are cleared are displayed, not just the count.

### Examples

- The following command displays RSVP session information:

```
switch>show mpls rsvp session
Session #1
 Destination address: 4.4.4.4
 Tunnel ID: 0
 Extended Tunnel ID: 1.1.1.1
 Role: transit
 LSP #1
 State: up
 Type: primary
 Source address: 1.1.1.1
 LSP ID: 1
 LSP uptime: 00:02:38
 Session name: Session1
 Local label: 100000
 Downstream label: 100000
 Upstream neighbor: 10.0.1.1
 Last refresh received: 17 seconds ago
 Last refresh sent: 10 seconds ago
 Downstream neighbor: 10.0.2.2
 Last refresh received: 7 seconds ago
 Last refresh sent: 9 seconds ago
 Bypass tunnel: not requested switch>
```

- The following command displays detailed RSVP session information:

```
switch>show mpls rsvp session detail
Session #1
 Destination address: 4.4.4.4
 Tunnel ID: 0
 Extended Tunnel ID: 1.1.1.1
```

```

Role: transit
LSP #1
 State: up
 [...]
 MTU Signaling: enabled
 Received Path MTU: 1800 bytes
 Sent Path MTU: 1500 bytes
 [...]
switch>

```

- The following command displays history information for RSVP sessions and LSPs:

```

switch>show mpls rsvp session history
Session #0, Session1
Tue 2024-06-04 17:25:33.708 Session created
Tue 2024-06-04 17:25:33.708 LSP #2 added
LSP #2
Tue 2024-06-04 17:25:33.714 State change: down (path: received-only, resv:
down)
Tue 2024-06-04 17:25:33.721 Bandwidth state change: pending on Ethernet2
Tue 2024-06-04 17:25:33.721 State change: path-only (path: up, resv: down)
Tue 2024-06-04 17:25:33.767 State change: path-only (path: up, resv:
received-only)
Tue 2024-06-04 17:25:33.776 Bandwidth state change: reserved on Ethernet2
Tue 2024-06-04 17:25:33.777 State change: up
Tue 2024-06-04 17:25:33.802 FRR bypass (link): available, via 10.0.25.5
switch>

```

- The following command displays a summary of RSVP session information:

```

switch>show mpls rsvp session summary
Session Destination LSP Name
 Role Bypass State
=====
1 4.4.4.4 1 Session1
transit n/req up switch>

```

---

## 20.4.50 show rib system-tunneling-ldp-rib route ip

The `show rib system-tunneling-ldp-rib route ip` command shows RSVP tunnel next hop resolutions for LDP.

### Command Mode

EXEC

### Command Syntax

```
show rib system-tunneling-ldp-rib route ip
```

### Examples

This command shows RSVP tunnel next hop resolutions for LDP.

```
switch# show rib system-tunneling-ldp-rib route ip
VRF: default
Codes: I L1 - IS-IS level 1, I L2 - IS-IS level 2
Gateway of last resort is not set
 I L2 5.5.5.5/32 [115/20] via 5.5.5.5/32, RSVP LER tunnel index 1
 via 10.0.25.5, Ethernet4, label imp-null(3)
 via 5.5.5.5/32, RSVP LER tunnel index 2
 via 10.0.23.3, Ethernet2, label 116384
 I L2 6.6.6.6/32 [115/30] via 5.5.5.5/32, RSVP LER tunnel index 1
 via 10.0.25.5, Ethernet4, label imp-null(3)
 via 5.5.5.5/32, RSVP LER tunnel index 2
 via 10.0.23.3, Ethernet2, label 116384
 I L2 10.0.56.0/24 [115/20] via 5.5.5.5/32, RSVP LER tunnel index 1
 via 10.0.25.5, Ethernet4, label imp-null(3)
 via 5.5.5.5/32, RSVP LER tunnel index 2
 via 10.0.23.3, Ethernet2, label 116384
```

## 20.4.51 show traffic-engineering cspf path

The `show traffic-engineering cspf path` command displays all the paths counted by CSPF.

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering cspf path [destination-IP <IP address>] [detail]
```

`show traffic-engineering cspf path ( <ipv4> | <path-id> | tunnel-name <name> ) [ detail ]` - A path or tunnel name can be specified.

`show traffic-engineering cspf path p2mp ( <path-id> | tunnel-name <name> ) [ detail ]` - A P2MP version of the command is also available.

`show traffic-engineering cspf path <ipv4> links` - Displays the link attributes of the links on all the CSPF paths with a given destination IP address.

### Parameters

**A.B.C.D** - CSPF path to this destination IP address.

**detail** - Shows detailed path information.

**links**

**p2mp**

**tunnel-name**

### Example

- An example of the output of the `show traffic-engineering cspf path` command.

```
switch> show traffic-engineering cspf path
Destination Path ID Constraint Path
10.2.2.2 0 bandwidth 150.00 Mbps
 10.0.2.2
 setup priority 4
 10.0.3.2
 share bandwidth with path 10.3.3.3 ID 2
 share bandwidth with path 10.4.4.4 ID 0
 10.3.3.3 2 bandwidth 150.00 Mbps
 10.0.4.2
 setup priority 4
 10.0.5.2
 share bandwidth with path 10.2.2.2 ID 0
 share bandwidth with path 10.4.4.4 ID 0
 10.4.4.4 0 bandwidth 150.00 Mbps
 10.0.6.2
 setup priority 4
 10.0.7.2
 share bandwidth with path 10.2.2.2 ID 0
 share bandwidth with path 10.3.3.3 ID 2
```

- An example of the output of the `show traffic-engineering cspf path detail` command.

```
switch> show traffic-engineering cspf path detail
Destination: 10.2.2.2
Path ID: 0
```

---

```

Path Constraint: bandwidth 150.00 Mbps

```

## 20.4.52 show traffic-engineering database

Use the **show traffic-engineering database** to display the topology used for CSPF computations. Starting from *EOS Release 4.23.1F*, the SRLG group details of a neighbor are shown if it is advertised.

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering database
```

### Special Considerations

- Beginning with *EOS Release 4.23.1F*, the SRLG group details of a neighbor are shown if it is advertised.
- Beginning with *EOS Release 4.24.2F*, information for the OSPFv2 topology is displayed if configured.

### Example

```
switch# show traffic-engineering database

TE Router-ID: 1.0.0.2
 Source: IS-IS Level-1 IPv4 Topology Database
 IS-IS System-ID: 1111.1111.1001

## 20.4.53 show traffic-engineering rsvp tunnel detail

The `show traffic-engineering rsvp tunnel detail` command shows RSVP tunnel detail including LDP tunneling eligibility.

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering rsvp tunnel detail
```

### Parameters

### Examples

The `show traffic-engineering rsvp tunnel detail` command shows RSVP tunnel detail including LDP tunneling eligibility.

```
switch>show traffic-engineering rsvp tunnel detail
Tunnel tunnel2to5
 Source: 2.2.2.2
 Destination: 5.5.5.5
 State: up
 Bandwidth: 0.0 bps, mode explicit
 Setup priority: 7
 Hold priority: 0
 MTU signaling: disabled
 Periodic optimization: disabled
 Session #1
 Tunnel index: 1
 LSPs: 1
 LDP tunneling: enabled
 IGP shortcut: disabled
 Active path: primary
 Primary path: path2to5
 State: up, in use
 Path (explicit):
 10.0.25.5
Tunnel tunnel2to5via3
 Source: 2.2.2.2
 Destination: 5.5.5.5
 State: up
 Bandwidth: 0.0 bps, mode explicit
 Setup priority: 7
 Hold priority: 0
 MTU signaling: disabled
 Periodic optimization: disabled
 Session #2
 Tunnel index: 2
 LSPs: 1
 LDP tunneling: enabled
 IGP shortcut: disabled
 Active path: primary
 Primary path: path2to5via3
 State: up, in use
 Path (explicit):
 10.0.23.3
 10.0.35.5
```

---

## 20.4.54 show traffic-engineering rsvp tunnel history

Display the history of a RSVP tunnel. For information about the detail version of this command, refer to [show traffic-engineering rsvp tunnel detail](#).

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering rsvp tunnel history
```

### Parameters

### Example

The following example displays the history of a RSVP tunnel named TestTunnel.

```
switch> show traffic-engineering rsvp tunnel history
Tunnel TestTunnel
Mon 2020-07-13 07:04:44 CSPF query on primary path
Mon 2020-07-13 07:04:44 State change: down
Mon 2020-07-13 07:04:44 LSP #1 added
Mon 2020-07-13 07:04:44 CSPF reply for primary path, path found
Mon 2020-07-13 07:04:44 LSP #2 added
Mon 2020-07-13 07:04:46 State change: up using primary path
LSP #1
Mon 2020-07-13 07:04:44 LSP created
Mon 2020-07-13 07:04:44 State change: establishing
Mon 2020-07-13 07:04:46 State change: up
LSP #2
Mon 2020-07-13 07:04:44 LSP created
Mon 2020-07-13 07:04:44 State change: establishing
Mon 2020-07-13 07:04:47 State change: up
```

## 20.4.55 show traffic-engineering rsvp tunnel lsp

Display RSVP tunnel LSPs using the `show traffic-engineering rsvp tunnel lsp` command.

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering rsvp tunnel lsp
```

### Parameters

### Example

The following example displays RSVP tunnel LSPs.

```
switch> show traffic-engineering rsvp tunnel lsp
Tunnel TestTunnel
 Source: 10.1.1.1
 Destination: 10.4.4.4
 Color: 60, Metric: 0
 State: up
 Bandwidth: 0.0 bps, mode explicit
 LSPs: 2
 Active path: primary
 LSP 1:
 Path specification: Path2to4, primary
 CSPF Path ID: 10001
 Bandwidth: 0.0 bps
 State: up, in use
 Path (dynamic):
 10.0.12.2
 10.0.23.3
 10.0.34.4
 LSP 2:
 Path specification: Path2to4detour, secondary
 Bandwidth: 0.0 bps
 State: up
 Path (explicit):
 10.0.16.6
 10.0.67.7
 10.0.37.3
 10.0.34.4
```

---

## 20.4.56 show traffic-engineering rsvp tunnel name

Display the status of a specific RSVP tunnel, using the name of the tunnel with the **show traffic-engineering rsvp tunnel name** command.

A variation of the command is **show traffic-engineering rsvp tunnel name *MyTunnel*** which can then be appended with

- **detail**
- **history**
- **Isp**
- **sub-tunnel**
- **summary** - Can be used with or without a filter. **With** the filter you only get that tunnel, **without** the filter you get **all** tunnels.

### Command Mode

EXEC

### Command Syntax

**show traffic-engineering rsvp tunnel name<name of tunnel>**

### Parameters

### Example

The following command displays the status of a specific RSVP tunnel.

```
switch>show traffic-engineering rsvp tunnel name MyTunnel
! RSVP is not enabled
! MPLS routing is not enabled
! Traffic engineering is not enabled
! Agent RSVP is not running
! Agent MPLS is not running
```

## 20.4.57 show traffic-engineering rsvp tunnel sub-tunnel summary

Display split tunnel information in a summarized fashion using the **show traffic-engineering rsvp tunnel sub-tunnel summary** command.

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering rsvp tunnel sub-tunnel summary
```

### Parameters

### Example

The following example displays split tunnel information in a summarized fashion.

```
switch> show traffic-engineering rsvp tunnel sub-tunnel summary
Tunnel: TestSplitTunnelUp
Sub Tunnel Session ID Index Active Path Bandwidth LSPs State
===== ====== ===== ========= ===== ===== =====
1 65535 123456 primary 19.2 Kbps 1 up
2 65535 123460 secondary 19.2 Kbps 1 up
Tunnel: TestSplitTunnelUp-2
Sub Tunnel Session ID Index Active Path Bandwidth LSPs State
===== ====== ===== ========= ===== ===== =====
1 65535 123457 secondary 19.2 Kbps 1 up
```

---

## 20.4.58 show traffic-engineering rsvp tunnel summary

Display a summary of the status of an RSVP tunnel using the **show traffic-engineering rsvp tunnel summary** command.

**Command Mode**

EXEC

**Command Syntax**

```
show traffic-engineering rsvp tunnel summary
```

**Parameters**

**Example**

The following example displays a summary of the status of an RSVP tunnel.

```
switch> show traffic-engineering rsvp tunnel summary
Tunnel Name Destination Color Index Active Path Reserved BW LSPs State
===== ====== ===== = ===== ===== ===== ===== ===== =====
TestTunnel 10.4.4.4 60 - primary 0.0 bps 2 up
```

## 20.4.59 show traffic-engineering rsvp tunnel

Display the traffic engineering RSVP tunnel status using the **show traffic-engineering rsvp tunnel** command.

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering rsvp tunnel
```

### Parameters

### Example

The following example displays the traffic engering RSVP tunnel status.

```
switch> show traffic-engineering rsvp tunnel
Tunnel TestTunnel
 Source: 10.1.1.1
 Destination: 10.4.4.4
 Color: 60, Metric: 0
 State: up
 Bandwidth: 0.0 bps, mode explicit
 LSPs: 2
 Active path: primary
 Primary path: Path2to4
 State: up, in use
 Path (dynamic):
 10.0.12.2
 10.0.23.3
 10.0.34.4
 Secondary path: Path2to4detour
 State: up
 Path (explicit):
 10.0.16.6
 10.0.67.7
 10.0.37.3
 10.0.34.4
```

---

## 20.4.60 show traffic-engineering rsvp

The **show traffic-engineering rsvp** command displays the current status of traffic engineering RSVP.

### Command Mode

EXEC

### Command Syntax

```
show traffic-engineering rsvp
```

### Parameters

### Example

The following example displays the current status of traffic engineering RSVP.

```
switch> show traffic-engineering rsvp
Local interface: 'Loopback0'
IP address: 10.1.1.1
Number of tunnels: 1
Operational: 1
Secondary path enabled: 1
Secondary path in use: 0
Number of LSPs: 2
Operational: 2
```

## 20.4.61 shutdown (MPLS RSVP)

The **shutdown** command disables the RSVP-TE protocol instance. This command allows shutting down RSVP, but retaining the configuration in the MPLS RSVP config mode, as opposed to **default mpls rsvp** or **no mpls rsvp**, which would disable RSVP but also wipe the config.

RSVP-TE is enabled globally by issuing **no shutdown** in the configuration sub-mode. RSVP also needs MPLS to be enabled globally. There is no per-interface knob to enable or disable RSVP. However, RSVP will not work on interfaces on which MPLS is disabled with **no mpls ip**.

### Command Mode

MPLS RSVP Configuration

### Command Syntax

```
shutdown
no shutdown
```

### Examples

- The following example enables RSVP-TE globally with the **no shutdown** command.

```
switch(config-mpls-rsvp) # no shutdown
```

- The following example disables RSVP-TE globally with the **shutdown** command, which is the default.

```
switch(config-mpls-rsvp) # shutdown
```

---

## 20.4.62 shutdown (tunnel)

A tunnel is not enabled by default, it must be explicitly enabled using the **no shutdown** command.

Changes made in the Tunnel submode only take effect when the exited normally, using the **exit** command. Changes made in the Tunnel submode are discarded using the **abort** command.

### Command Mode

Traffic Engineering RSVP Tunnel Configuration

### Command Syntax

**no shutdown**

### Parameters

### Example

- The following example enables a tunnel.

```
switch(config-te-rsvp-tunnel-MyTunnel) # no shutdown
```

- The following example exits the tunnel and makes changes effective.

```
switch(config-te-rsvp-tunnel-MyTunnel) # exit
switch(config-te-rsvp) #
```

- The following example discards changes.

```
switch(config-te-rsvp-tunnel-MyTunnel) # abort
switch(config-te-rsvp) #
```

## 20.4.63 split-tunnel

The **split-tunnel** command enables and configures RSVP sub-tunnels. Using the **quantum** keyword enables fixed-bandwidth sub-tunnels. Specifying a bandwidth minimum and maximum enables adaptive sub-tunnels which grow or shrink in response to changes in bandwidth.

The **no split-tunnel** and **default split-tunnel** commands disable adaptive split tunnels for the configuration-mode tunnel.

### Command Mode

Traffic Engineering RSVP Tunnel Configuration

### Command Syntax

```
split-tunnel (disabled | (min bandwidth_num bandwidth_units max bandwidth_num bandwidth_units [sub-tunnels limit max_tunnels] [reduction-delay time time_units]) | (quantum bandwidth_num bandwidth_units [sub-tunnels limit max_tunnels]))
```

```
no split-tunnel
```

```
default split-tunnel
```

### Parameters

- **disabled** - Disables adaptive split tunnels for the configuration-mode tunnel.
- **min *bandwidth\_num units*** - Configures the minimum bandwidth for each sub-tunnel. Values range from 0.00 to 1000.00 and the units may be **bps**, **kbps**, **mbps**, or **gbps**.
- **max *bandwidth\_num units*** - Configures the maximum bandwidth for each sub-tunnel. Values range from 0.00 to 1000.00 and the units may be **bps**, **kbps**, **mbps**, or **gbps**.
- **sub-tunnels limit *max\_tunnels*** - Optionally limits the number of sub-tunnels to **max\_tunnels**. Values range from 1 to 100. The default value is 10.
- **reduction-delay *time time\_units*** - Optionally configures the amount of time before unused sub-tunnels are removed when traffic drops. Values range from 1 to 9999 and the units may be **hours**, **minutes**, or **seconds**. Default delay is 1 hour.
- **quantum *bandwidth\_num units*** - Enables fixed-bandwidth sub-tunnels and specifies the bandwidth to reserve for each tunnel. Values range from 0.00 to 1000.00 and the units may be **bps**, **kbps**, **mbps**, or **gbps**.

### Examples

- The following commands enable a maximum of 20 sub-tunnels with a bandwidth of 500 kilobits per second on RSVP tunnel `tunnel17`:

```
switch(config-te-rsvp)#tunnel tunnel17
switch(config-te-rsvp-tunnel-tunnel17)#split-tunnel quantum 500 kbps sub-tunnels limit 20
switch(config-te-rsvp-tunnel-tunnel17) #
```

- The following commands enable a maximum of 75 adaptive sub-tunnels that can vary between 500 kilobits per second and 100 gigabits per second on RSVP tunnel `tunnel17`

```
switch(config-te-rsvp)#tunnel tunnel17
switch(config-te-rsvp-tunnel-tunnel17)#split-tunnel min 500 kbps max 100 gbps sub-tunnels limit 75
switch(config-te-rsvp-tunnel-tunnel17) #
```

---

## 20.4.64 srlg

The **srlg** command specifies if link SRLGs of a primary LSP are to be considered as constraints while creating a fast-reroute bypass tunnel with either link or node protection. When the **srlg** command is entered with the **strict** option, then when a path for a bypass tunnel excluding SRLGs of the next-hop interface of the primary LSP can not be found, RSVP does not set up the bypass tunnel. When the **srlg** command is entered without the **strict** option, then a bypass tunnel is set up with as many links as possible that exclude the SRLGs of the next-hop interface of the primary LSP. Where such links are not available, links that have the least number of SRLGs which are to be excluded are used.

The **no srlg** and **default srlg** commands restore the default state by turning off SRLG processing.

### Command Mode

MPLS RSVP Configuration

### Command Syntax

**srlg [strict]**

**no srlg**

**default srlg**

### Parameters

**strict** - Applies strict SRLG constraints.

### Example

- The following commands enable SRLG processing:

```
switch(config)#mpls rsvp
switch(config-mpls-rsvp)#srlg
switch(config-mpls-rsvp) #
```

## 20.4.65 neighbor <IP> targeted

The **neighbor <IP> targeted** command is used to configure a targeted adjacency with a non-adjacent router from the LDP configuration mode. Both peers require the targeted adjacency configuration because a targeted adjacency is not accepted from an unknown LSR by default.

**Note:** This configuration may not be required because the targeted adjacency will be established automatically by both peers based on the RSVP tunnel configuration.

### Command Mode

MPLS-LDP Configuration

### Command Syntax

```
neighbor ip_address targeted
no neighbor ip_address targeted
default neighbor targeted
```

### Parameter

***ip\_address*** - The IP address of the neighbor to establish a targeted adjacency with.

### Examples

The following example configures a targeted adjacency with a non-adjacent router (neighbor 5.5.5.5).

```
switch(config-mpls-ldp)# neighbor 5.5.5.5 targeted
```

---

## 20.4.66 timer recovery

This command will have a different behavior depending on the command mode (speaker or helper).

The **timer recovery** command configures the maximum accepted MPLS RSVP recovery time. This is the set maximum that will be used if the neighbor wants an even higher timer.

The **no timer recovery** and **default timer recovery** commands restore the maximum recovery timer value to its default. In speaker mode, the default maximum is 90 seconds. In helper mode, the default is to accept all maximum recovery time values.

### Command Mode

- MPLS RSVP Graceful Restart Helper Configuration
- MPLS RSVP Graceful Restart Speaker Configuration
- MPLS RSVP Hitless Restart Configuration

Example to enter configuration mode:

```
graceful-restart role {helper | speaker}
```

### Command Syntax

```
timer recovery numseconds
no timer recovery
default timer recovery
```

### Helper Configuration Mode

**timer recovery maximum <t> seconds** - The maximum accepted recovery time value, configured under helper configuration mode.

```
default timer recovery maximum <t> seconds
no timer recovery maximum <t> seconds
```

### Speaker Configuration Mode

**timer recovery <t> seconds** - The requested recovery time value is configurable under the speaker configuration mode.

### Parameters

- **num** - Maximum recovery time in seconds. Values range from 1 to 320. The default is 90 seconds in speaker mode.

### Example

The following command configures the recovery timer to 45 seconds in RSVP for a switch in MPLS RSVP Graceful Restart Speaker mode:

```
switch(config-mpls-rsvp-gr-speaker)#timer recovery 45 seconds
switch(config-mpls-rsvp-gr-speaker) #
```

## 20.4.67 timer restart

The **timer restart** command configures a maximum acceptable value for RSVP graceful restart timers received from RSVP neighbors. This is the set maximum that will be used if the neighbor wants an even higher timer.

The **no timer restart** and **no timer restart** commands restore the maximum restart time value to its default. In speaker mode, the default requested is 90 seconds. In helper mode, the default is to accept all maximum restart time values.

### Command Mode

- MPLS RSVP Graceful Restart Helper Configuration
- MPLS RSVP Graceful Restart Speaker Configuration
- MPLS RSVP Hitless Restart Configuration
- 

Example to enter configuration mode:

```
graceful-restart role {helper | speaker}
```

### Command Syntax

#### Helper Configuration

**timer restart maximum <t> seconds** - The maximum accepted restart time value is configurable under helper configuration mode.

```
default timer restart maximum <t> seconds
```

```
no timer restart maximum <t> seconds
```

#### Speaker Configuration

**timer restart <t> seconds** - The restart time value is configurable under the speaker configuration mode.

```
default timer restart <t> seconds
```

```
no timer restart <t> seconds
```

**timer recovery <t> seconds** - The recovery time value is configurable under the speaker configuration mode.

### Parameters

- **num** - Maximum accepted recovery time in seconds. Values range from 1 to 320. The default is 90 seconds in speaker mode.

### Example

The following command configures the restart timer to 45 seconds in RSVP for a switch in MPLS RSVP Graceful Restart Speaker mode:

```
switch(config-mpls-rsvp-gr-speaker) #timer restart 45 seconds
switch(config-mpls-rsvp-gr-speaker) #
```

---

## 20.4.68 traffic-engineering srlg

The **traffic-engineering srlg** command configures a shared risk link group (SRLG) for the command-mode interface.

The **no traffic-engineering srlg** and **default traffic-engineering srlg** commands remove the SRLG configuration from the interface.

### Command Mode

Interface Configuration

### Command Syntax

```
traffic-engineering srlg (srlg_name|srlg_group_ID)
no traffic-engineering srlg (srlg_name|srlg_group_ID)
default traffic-engineering srlg (srlg_name|srlg_group_ID)
name
```

### Parameters

- ***srlg\_name*** - Name of the SRLG.
- ***srlg\_group\_ID*** - Group ID of the SRLG. Values range from 0 to 4294967295.

### Example

The following commands configure SRLG 29975 on Ethernet interface 1/1:

```
switch(config)#interface ethernet 1/1
switch(config-if-Et1/1)#traffic-engineering srlg 29975
switch(config-if-Et1/1)#{
```

## 20.4.69 tunnel

The **tunnel** command enters Traffic Engineering RSVP Tunnel configuration mode for the named tunnel. If the named tunnel does not exist, the command creates it.

**Note:** The **no** and **default** forms of the command delete the named tunnel from running config.

Entering the **p2mp** keyword after the name of the tunnel places the tunnel into peer-to-multipoint (p2mp) mode.

**Note:** No P2P and P2MP tunnels with the same name can exist at the same time.

### Command Mode

Traffic Engineering RSVP Configuration

### Command Syntax

```
tunnel name [p2mp]
no tunnel name [p2mp]
default tunnel name [p2mp]
```

### Parameters

**p2mp** - Places the tunnel into peer-to-multipoint (p2mp) mode.

### Example

The following example enters the configuration mode for the tunnel named MyTunnel:

```
switch(config-te-rsvp)# tunnel MyTunnel
switch(config-te-rsvp-tunnel-MyTunnel) #
```

---

## 20.4.70 tunneling ldp

LDP over RSVP is configured by enabling the **tunneling ldp** command. When enabled, the **tunneling ldp** command causes the RSVP tunnel to become eligible for LDP over RSVP.

To disable LDP over RSVP on the tunnel use the **default tunneling** command.

### Command Mode

Traffic Engineering RSVP Tunnel Configuration

### Command Syntax

**tunneling ldp**

### Parameters

### Example

The following example configures LDP over RSVP.

```
switch(config-te-rsvp-tunnel-MyTunnel)# tunneling ldp
```

## 20.4.71 tunneling ldp ucmp

The `tunneling ldp ucmp` command configures UCMP with LDP over RSVP.

**Note:** This configuration may not be required because the targeted adjacency will be established automatically by both peers based on the RSVP tunnel configuration .

### Command Mode

RSVP tunnel configuration mode

### Command Syntax

```
tunneling ldp ucmp
```

### Parameter

**bandwidth 20 gbps** - The bandwidth configured on the RSVP tunnel determines the weight associated with this tunnel when traffic to the tunnel endpoint is UCMP load balanced.

**bandwidth signalling disabled** - The bandwidth configured on RSVP tunnels is both signalled and used as the UCMP weight. Use this command, to specify bandwidths on RSVP tunnels to be used only as the UCMP weight without signalling the bandwidths in RSVP.

### Examples

- The following example configures a targeted adjacency with a non-adjacent router.

```
switch(config-te-rsvp-tunnel-tunnelABC) # tunneling ldp ucmp
```

- The following example configures the RSVP tunnel bandwidth.

```
switch(config-te-rsvp-tunnel-tunnelABC) #bandwidth 20 gbps
```

- The following example disables signalling.

```
switch(config-te-rsvp-tunnel-tunnelABC) #bandwidth signalling disabled
```

## Visibility and Monitoring Services

---

The Visibility and Monitors Services chapter contains the following sections:

- [Test Access Point Aggregation](#)
- [Latency Analyzer \(LANZ\)](#)
- [Sampled Flow Tracking](#)
- [sFlow](#)
- [SNMP](#)
- [VM Tracer](#)
- [MapReduce Tracer](#)
- [Transceiver Performance Monitoring](#)
- [NDR Sensor](#)
- [Connectivity Monitor](#)

### 21.1 Test Access Point Aggregation

This section describes Test Access Point (TAP) aggregation and the data structures that it requires. Topics in this section include:

- [TAP Aggregation Introduction](#)
- [TAP Aggregation Description](#)
- [TAP Aggregation Extra MPLS Pop \(4 to 6 Labels\)](#)
- [TAP Aggregation Configuration](#)
- [TAP Aggregation Traffic Steering](#)
- [TAP Aggregation GUI](#)
- [TAP Aggregation Keyframe and Timestamp Configuration](#)
- [TapAgg GRE Tunnel Termination](#)
- [Tap Aggregation Hardware Forwarding Profile](#)
- [TAP Aggregation MPLS Pop](#)
- [TAP Aggregation 802.1br EVN Tag Stripping](#)
- [TAP Aggregation Commands](#)

#### 21.1.1 TAP Aggregation Introduction

Ethernet-based switches are commonly deployed in dedicated networks to support Test Access Point (TAP) and mirror port traffic toward one or more analysis applications. Ports configured to mirror data can simultaneously switch traffic to its primary destination while directing a copy of that traffic to analysis or test devices. TAP ports are typically part of a dedicated environment that allows for the aggregation of data streams from multiple sources that can be directed to multiple destinations.

Arista switches support port mirroring and TAP aggregation and the data structures required by these functions.

## 21.1.2 TAP Aggregation Description

These sections describe TAP aggregation, timestamps, and keyframes:

- [TAP Aggregation](#)
- [Timestamps and Keyframes](#)

### 21.1.2.1 TAP Aggregation

Test Access Point (TAP) aggregation is the accumulation of data streams and the subsequent dispersal of these streams to devices and applications that analyze, test, verify, parse, detect, or store data. TAP aggregation requires an environment free from switching operations. Arista switches operate in one of two device modes:

- **Switching mode:** the switch performs normal switching and routing operations. Data mirroring is supported in switching mode. Tap aggregation is not available in switching mode.
- **TAP aggregation mode:** The switch is a data-monitoring device and does not provide normal switching and routing services. Data mirroring is not available in tap aggregation mode.

Access control lists, port channels, LAGs, QoS, and VLANs function normally in both modes.

Ethernet and port channel interfaces are configured as **TAP** and **tool** ports to support tap aggregation.

- **TAP ports:** a tap port is an interface that receives a data stream that two network ports exchange. TAP ports prohibit egress traffic. MAC learning is disabled. All control plane interaction is prevented. Traps for inbound traffic are disabled. Tap ports are in STP forwarding mode.
  - **Tool ports:** A tool port is an interface that replicates data streams received by one or more tap ports. Tool ports connect to devices that process the monitored data streams.
- Tool ports prohibit ingress traffic. MAC learning is disabled. All control plane interaction is prevented. Tool ports are in STP forwarding mode.

TAP and tool ports are configured with the **switchport mode** command. These ports are active when the switch is in tap aggregation mode and error-disabled when the switch is in switching mode.

TAP and tool ports are designated through switchport mode commands and act similar to trunk ports, in that they can allow access to VLANs specified through allowed-VLAN lists. Tap ports also specify a native VLAN for handling untagged frames.

Access, trunk, and dot1q-tunnel mode ports are active when the switch is in switching mode and error-disabled when the switch is in tap aggregation mode.

TAP and tool mode ports are active when the switch is in TAP aggregation mode and error-disabled when the switch is in switching mode.

**TAP aggregation groups** are data structures that map a set of TAP ports to a set of tool ports. Both TAP and tool ports may belong to multiple TAP aggregation groups, and a TAP aggregation group may contain multiple TAP and tool ports.

### 21.1.2.2 Timestamps and Keyframes

FM6000 platform switches support packet timestamping of packets sent from any port at line rate. Timestamps are used to correlate network events and in performance analysis. Keyframes provide information to assist in the interpretation of timestamps.

The switch contains two 64-bit counters to maintain ASIC time and UTC time. ASIC time is based on an internal 350 MHz counter. UTC is absolute time that is maintained by a precision oscillator and synchronized through PTP.

---

Timestamps are derived from the least significant 31 bits of ASIC time. Based on the 350 MHz counter period and 31-bit resolution, timestamp values repeat every 6.135 seconds.

Keyframes are periodically inserted into the data stream to provide context for interpreting timestamps. Keyframes contain the 64-bit value of the ASIC time counter, the corresponding 64-bit value of the UTC time counter, and the elapsed time since the last PTP synchronization of the UTC counter. Inserting one keyframe every second into the data stream assures that the timestamp value in each egress packet can be associated with values of the complete 64-bit ASIC time counter and the corresponding UTC counter.

#### 21.1.2.2.1 Timestamps

Timestamps are based on a frame's ingress time and applied to frames sent on egress ports, ensuring that timestamps on monitored traffic reflect ingress timing of the original frames. Timestamping is configured on the egress port where the timestamp is applied to the frame.

A timestamp consists of the least significant 31 bits of the ASIC time counter. The most significant bit of the least significant byte is a 0 pad, resulting in a 32-bit timestamp with 31 bits of data. The keyframe mechanism provides recovery of the most significant 33 bits of the ASIC counters and a map to UTC time. Applications use this mechanism to determine the absolute time of the frame timestamp.

The switch supports three timestamp modes, which are configurable on individual Ethernet ports. The modes differ in the management of the egress frame's 32-bit frame check sequence (FCS):

- **Disabled:** timestamping is disabled.
- **FCS Replacement Mode:** the original FCS is discarded, and the ingress timestamp is appended to frame data, followed by a new FCS that is based on the appended timestamp. The result is a valid Ethernet frame, but the headers of all nested protocols are not updated to reflect the timestamp.
- **FCS Appending Mode:** the original FCS is discarded and replaced by the ingress timestamp. The size of the original frame is maintained without any latency impact, but the FCS is not valid.

#### 21.1.2.2.2 Keyframes

Keyframes contain routable IP packets that provide information to relate timestamps with the complete ASIC counter and absolute UTC time. Keyframes have valid L2 and L3 headers. Keyframes contain these header fields:

- MAC fields (12 bytes):
  - Source MAC address is the address of the egress interface transmitting the keyframe.
  - Destination MAC address is configured through a CLI command.
- IP Header (20 bytes):
  - Source IP address is configured through CLI; default is management interface IP address.
  - Destination IP address is configured through a CLI command.
  - TTL is set to **64**.
  - TOS is set to **0**.
  - Protocol field is set to **253**.
  - IP header's ID field is set to **0**.

Keyframes contain these payload fields:

- **ASIC time:** (64 bits) ASIC time counter. (**2.857** ns resolution).
- **UTC time:** (64 bits) Unix time that corresponds to ASIC time (ns).
- **Last sync time:** (64 bits) ASIC time of most recent PTP synchronization.
- **Keyframe time:** (64 bits) ASIC time of the keyframe's egress (ns).

- **Egress interface drops:** (64 bits) Number of dropped frames on keyframe's egress interface.
- **Device ID:** (16 bits) device ID (user defined).
- **Egress interface:** (16 bits) Keyframe's egress switchport.
- **FCS type (8 bits):** Timestamping mode configured on keyframe's egress port.
  - **0:** timestamping disabled.
  - **1:** timestamp is appended to payload; new FCS is added to the frame.
  - **2:** timestamp overwrites the existing FCS.
- **Reserved (8 bits):** reserved for future use.
- **Skew numerator/skew denominator:** form a ratio indicating the ASIC clock skew. If the ratio is greater than **1**, the clock is skewed fast; if the ratio is less than **1**, the clock is skewed slow.

Last sync time equals **0** when there was no previous synchronization or the time since the last synchronization is greater than **8** hours.

The 31-bit frame timestamp provides high-resolution timing, rolling over about every **6.135** seconds (31 bits at 2.857ns per tick). To obtain the full ASIC time and to correlate the timestamp to an absolute UTC time, the switch sends keyframes. Each keyframe contains the current ASIC time and UTC time; hence an application can compute the high order bits of the ASIC time (for precise, relative timing) from the ASIC to UTC time mapping, and then determine absolute time.

ASIC to UTC time conversion is not quite immediate, so the UTC time in the frame will not be the current time. A keyframe timestamp is provided for this purpose. The frame also includes the timestamping mode (FCS type) so applications can dynamically determine the timestamp's byte offset. Each field is shown in the following table.

**Table 138: Keyframe Payload**

|                    |          |                  |
|--------------------|----------|------------------|
| 0 7                | 8 15     | 16 31            |
| ASIC time          |          |                  |
| UTC time           |          |                  |
| Last sync time     |          |                  |
| Skew numerator     |          |                  |
| Skew denominator   |          |                  |
| Keyframe timestamp |          |                  |
| Drop count         |          |                  |
| Device ID          |          | Egress interface |
| FCS type           | Reserved |                  |

## 21.1.3 TAP Aggregation Extra MPLS Pop (4 to 6 Labels)

Available starting with *EOS Release 4.23.1F* extra MPLS pop for TAP Aggregation allows you to remove four to six MPLS labels from a packet. Previously, only one to three labels were able to be popped.

When configured, popping four to six MPLS labels works in all the cases where popping one to three MPLS labels works.

### 21.1.3.1 TAP Aggregation Extra MPLS Pop Configuration

MPLS pop is configurable per tap port as follows to pop one to three labels:

## Example

```
(config-if-Et1/1) # switchport tap mpls pop all
```

However, MPLS pop for four to six labels requires a user defined TAP Aggregation profile based on off of tap-aggregation-extended. This profile must have one action and three fields configured under the tapagg port feature, such as the following:

## Example

```
(config) # hardware tcam
(config-hw-tcam) # profile foo copy tap-aggregation-extended
(config-profile-foo) # feature tapagg port
(config-profile-foo-feature-tapagg-port) # action set-fwd-header
(config-profile-foo-feature-tapagg-port) # key field mpls-label1-lower-24b mpls-label2-lower-24b
 mpls-label3-lower-24b
(config-profile-foo-feature-tapagg-port) # tap aggregation
Saving new profile 'foo'
(config-tap-agg) # mode exclusive profile foo
```

With the above profile changes, four to six MLPS label pop is additionally supported when the MPLS pop feature is configured on a tap port.

To check if a profile is installed correctly, use the **show hardware tcam profile** command.

## Example

```
(config-tap-agg) # show hardware tcam profile
```

Upon successful installation of a TAP Aggregation profile, you should see a display similar to the following:

## Example

```
Configuration Status
FixedSystem foo*
* configuration overridden by TapAgg
```

### 21.1.3.1.1 Configuring a Local LFIB Convergence Delay for Protected Node or Adjacency Segments

The Point of Local Repair (PLR) switches to the TI-LFA backup path on link failure or BFD neighbor failure but switches back to the post-convergence path once the PLR computes SPF and updates its LFIB. This sequence of events can lead to micro-loops in the topology if the PLR converges faster than other routers along the post-convergence path. So a configuration option is provided to apply a delay, after which the LFIB route being protected by the TI-LFA loop-free repair path will be replaced by the post-convergence LFIB route.

To configure a convergence delay only to LFIB routes that are being protected, the following command is used either in the router IS-IS mode or the router IS-IS address-family sub-mode. A default of 10 seconds is used when using the command without an explicitly specified delay.

## Example

```
switch(config-router-isisis-af) # timers local-convergence-delay [<delay_in_milliseconds>] protected-prefixes
```

### 21.1.3.2 Limitations

#### 21.1.3.2.1 IP Steering

IP steering does not work for MPLS packets with four or more labels. Currently, you must work around this limitation with a configuration similar to the [Configuration for IP Steering](#). This workaround does not work when MPLS pop is not enabled.

#### 21.1.3.2.2 Configuration for IP Steering

When MPLS pop is enabled, you can enable IP steering for up to six MPLS labels by adding an extra port into the configuration as a tap-tool port.

For example, you want to perform IP steering from interface **Ethernet1** to a set of interfaces and also want MPLS labels to be popped. Add a new interface **Ethernet2**, which will not receive any external traffic, as a tap-tool port with traffic loopback. Then configure **Ethernet1** to forward to **Ethernet2** as its default interface. The commands would look similar to the following:

#### Example

```
(config-if-Et2) # swi mode tap-tool
(config-if-Et2) # traffic-loopback source system device phy
(config-if-Et2) # int et1
(config-if-Et1) # swi tap default interface et2
```

All of **Ethernet1**'s old tool ports should be disabled and become **Ethernet2**'s tool ports. Then, all IP steering configuration that was originally meant to be between **ET1** and its old tool ports should be configured with **Ethernet2** in place of **Ethernet1**. Finally, configure MPLS pop on **Ethernet1**.

### 21.1.3.3 TAP Aggregation Extra MPLS POP (4 to 6 Labels) Commands

[show hardware tcam profile](#)

## 21.1.4 TAP Aggregation Configuration

These sections describe TAP aggregation configuration tasks:

- [Enabling Tap Aggregation Mode](#)
- [Tap Aggregation Mixed Mode](#)
- [Tap Port Configuration](#)
- [Tool Port Configuration](#)
- [Per-linecard TCAM Profile Configuration](#)
- [Two-Way Ports for Tap Aggregation](#)
- [Tap Aggregation QoS Handling on Tap Ports](#)
- [Identity VLAN Tagging](#)
- [Tap Aggregation Group Configuration](#)

### 21.1.4.1 Enabling Tap Aggregation Mode

The switch supports switching mode and TAP aggregation mode. In switching mode, normal switching and routing functions are supported while TAP aggregation functions are disabled. In TAP aggregation mode, TAP

---

aggregation functions are enabled while normal switching and routing functions are disabled. By default, the switch is in switching mode.

A ports switchport status depends on its switchport mode and the switch's TAP aggregation mode.

- **Tap aggregation mode enabled:** TAP and tool ports are enabled. Switching ports are errdisabled.
- **Tap aggregation mode disabled:** TAP and tool ports are errdisabled. Switching ports are enabled.

To enable the switch to carry out TAP aggregation, first enter TAP aggregation configuration mode using the [tap aggregation](#) command, then set the mode to [tap aggregationexclusive](#).

**Note:** The switch can also perform TAP aggregation in **mixed** mode. See [Mixed Mode Configuration](#).

### Example

These commands enter TAP aggregation configuration mode, then place the switch in TAP aggregation **exclusive** mode.

```
switch(config) # tap aggregation
switch(config-tap-agg) # mode exclusive
switch(config-tap-agg) # show active
 tap aggregation
 mode exclusive
switch(config-tap-agg) #
```

To return the switch to switching mode, remove the **mode** command from **running-config**.

### Examples

- These commands enter TAP aggregation configuration mode, then place the switch in switching mode.

```
switch(config) # tap aggregation
switch(config-tap-agg) # no mode
switch(config-tap-agg) # show active
switch(config-tap-agg) #
```

- These commands enter switching mode and remove all TAP aggregation configuration mode statements.

```
switch(config) # no tap aggregation
switch(config) #
```

## 21.1.4.2 TAP Aggregation Mixed Mode

On a modular switch, the user can configure TAP Aggregation on some linecards and leave other linecards to operate normally. This is referred to as TAP aggregation mixed mode.

- [Mixed Mode Platform Compatibility](#)
- [Mixed Mode Configuration](#)

### 21.1.4.2.1 Mixed Mode Platform Compatibility

The following platforms support TAP Aggregation Mixed Mode.

- DCS-7500R
- DCS-7500R2

#### 21.1.4.2.2 Mixed Mode Configuration

Complete the following steps to configure **Linecard 3** as a TAP aggregation linecard in mixed mode.

1. Enable the switch for configuration.

```
switch> configure terminal
```

2. Enable TAP aggregation.

```
switch(config)# tap aggregation
```

3. Enable TAP aggregation mixed mode, selecting the targeted linecard module using the TAP aggregation default.

```
switch(config-tap-agg)# mode mixed module linecard 3 tap-aggregation-default
```

**Note:** Changing modes may affect available functionality. Unsupported configuration elements will be ignored.

The profile selection in mixed mode is the same as in exclusive mode. The user can configure multiple linecards for TAP aggregation in mixed mode.

The user can check TAP Aggregation Mixed Mode status by executing the following show commands:

```
switch(config)# show running-config section tap
tap aggregation
 mode mixed module linecard 3 profile tap-aggregation-default
switch(config)#show hardware tcam profile
 Configuration Status
Linecard4 default default
Linecard3 default tap-aggregation-default
Linecard6 default default
switch(config)#

```

#### 21.1.4.3 TAP Port Configuration

TAP ports function when the switch is in TAP aggregation mode. TAP ports receive traffic for replication to one or more tool ports. In TAP aggregation mode, TAP ports are in STP forwarding state and prohibit egress traffic. MAC learning, control plane interaction and traps for inbound traffic are disabled.

TAP mode ports are configured through switchport mode commands. TAP mode command settings persist in **running-config** without taking effect when the switch is not in TAP aggregation mode or the interface is not in TAP aggregation mode.

This section describes the following tap port configuration steps.

- [Configuring an Interface as a TAP Mode Port](#)
- [TAP Port Allowed VLAN List Configuration](#)
- [TAP Port Native VLAN](#)
- [TAP Port Packet Truncation](#)

##### Configuring an Interface as a Tap Mode Port

Ethernet and port-channel interfaces are configured as TAP ports with the **switchport mode** command.

##### Example

These commands configure interface ethernet **41** through **43** as TAP mode ports.

```
switch(config)# interface ethernet 41-43
switch(config-if-Et41-43)# switchport mode tap
switch(config-if-Et41-43)# show interface ethernet 41-43 tap
Port Configured Status Native Id Truncation Default
Mode Mode Vlan Vlan Group

Et41 tap tap 1 1 0 ---
Et42 tap tap 1 1 0 ---
Et43 tap tap 1 1 0 ---
switch(config-if-Et41-43) #
```

## TAP Port Allowed VLAN List Configuration

By default, TAP mode interfaces handle tagged traffic for all VLANs. The command creates or modifies the set of VLANs for which a TAP port handles tagged traffic.

### Example

These commands create TAP-mode allowed VLAN lists for interface ethernet **41** through **43**.

```
switch(config)# interface ethernet 41
switch(config-if-Et41)# switchport tap allowed vlan 401-410
switch(config-if-Et41)# interface ethernet 42
switch(config-if-Et42)# switchport tap allowed vlan 411-420
switch(config-if-Et41)# interface ethernet 41-42
switch(config-if-Et41-42)# show active
interface Ethernet41
 switchport mode tap
 switchport tap allowed vlan 401-410
interface Ethernet42
 switchport mode tap
 switchport tap allowed vlan 411-420
switch(config-if-Et41-42) #
```

## TAP Port Native VLAN

Tap mode Interfaces associate untagged frames with the tap mode native VLAN. The [switchport tap native vlan](#) command specifies the TAP-mode native VLAN for the configuration-mode interface. The default TAP-mode native VLAN for all interfaces is **vlan 41**.

### Example

These commands assign **vlan 400** as the TAP-mode native VLAN for **interface ethernet 41**.

```
switch(config)# interface ethernet 41
switch(config-if-Et41)# switchport tap native vlan 400
switch(config-if-Et41)# show interface ethernet 41-43 tap
Port Configured Status Native Id Truncation Default
Mode Mode Vlan Vlan Group

Et41 tap tap 400 1 0 ---
Et42 tap tap 1 1 0 ---
Et43 tap tap 1 1 0 ---
switch(config-if-Et41) #
```

## TAP Port Packet Truncation

TAP ports can be configured to truncate inbound packets. The [switchport tap truncation](#) command configures the configuration-mode interface, as a TAP port, to truncate inbound packets to the specified packet size. By default, TAP ports do not truncate packets.

### Examples

- These commands configure **interface ethernet 41** to truncate packets to **150** bytes.

```
switch(config)# interface ethernet 41
switch(config-if-Et41)# switchport tap truncation 150
switch(config-if-Et41)# show interface ethernet 41-43 tap
Port Configured Status Native Id Truncation Default
Mode Mode Vlan Vlan Vlan Group

Et41 tap tap 400 1 150 ---
Et42 tap tap 1 1 0 ---
Et43 tap tap 1 1 0 ---
switch(config-if-Et41) #
```

- These commands configure **interface ethernet 41** to send complete packets for replication.

```
switch(config-if-Et41)# no switchport tap truncation
switch(config-if-Et41)# show interface ethernet 41 tap
Port Configured Status Native Id Truncation Default
Mode Mode Vlan Vlan Vlan Group

Et41 tap tap 400 1 0 ---
switch(config-if-Et41) #
```

#### 21.1.4.4 Tool Port Configuration

Tool ports replicate traffic received by TAP ports. Tool ports are mapped to the TAP ports through TAP aggregation groups. A tool port may belong to multiple aggregation groups and an aggregation group may contain multiple tool ports.

Tool ports function when the switch is in TAP aggregation mode. In this switch mode, tool ports are in STP forwarding state and ingress traffic is prohibited. MAC learning, control plane interaction, and traps for inbound traffic are disabled. All control plane interaction is prevented and L2 agents do not send PDUs to tool-mode interfaces. When the switch is in switching mode, tool ports are error-disabled.

Tool-mode ports are configured through switchport commands. Tool-mode command settings persist in **running-config** without taking effect when the switch is not in TAP aggregation mode or the interface is not in TAP aggregation mode.

This section describes the following tool port configuration steps.

- [Configuring an Interface as a Tool-mode Port](#)
- [Tool Port Allowed VLAN List Configuration](#)
- [Tool Port Packet Truncation](#)

#### Configuring an Interface as a Tool-mode Port

Ethernet and port channel interfaces are configured as tool ports with the [switchport mode](#) command.

#### Example

These commands configure port-channel interfaces **101** through **103** as tool-mode ports and display the result.

```
switch(config)# interface port-channel 101-103
switch(config-if-Po101-103)# switchport mode tool
switch(config-if-Po101-103)# show interface port-channel 101-103 tool
Port Configured Status Allowed Id Timestamp
Mode Mode Vlans Tag Tag Mode

Po101 tool tool All Off ---
Po102 tool tool All Off ---
Po103 tool tool All Off ---
switch(config-if-Po101-103) #
```

## Tool Port Allowed VLAN List Configuration

By default, tool mode interfaces handle tagged traffic for all VLANs. The [switchport tool allowed vlan](#) command creates or modifies the set of VLANs for which a tool port handles tagged traffic.

### Example

These commands create tool mode allowed VLAN lists for port-channel interfaces 101 through 103.

```
switch(config)# interface port-channel 101-103
switch(config-if-Po101-103)# switchport tool allowed vlan 1010-1020
switch(config-if-Po101-103)# interface port-channel 101
switch(config-if-Po101)# switchport tool allowed vlan add 1001-1009
switch(config-if-Po103)# interface port-channel 102
switch(config-if-Po102)# switchport tool allowed vlan remove 1016-1020
switch(config-if-Po102)# interface port-channel 103
switch(config-if-Po103)# switchport tool allowed vlan add 1021-1030
switch(config-if-Po103)# show interface port-channel 101-103 tool
Port Configured Status Allowed Id Timestamp
Mode Mode Vlans Tag Mode

Po101 tool tool 1001-1020 Off ---
Po102 tool tool 1010-1015 Off ---
Po103 tool tool 1010-1030 Off ---
switch(config-if-Po103)#

```

## Tool Port Packet Truncation

Tool ports can be configured to truncate outbound packets. The [switchport tool truncation](#) command configures the configuration-mode interface, as a tool port, to truncate outbound packets to **160** bytes. By default, tool ports do not truncate packets.

Tool port packet truncation is supported only on the 7150 series platform.

### Examples

- These commands configure **interface ethernet 41**, as a tool port, to truncate packets on egress to **160** bytes.

```
switch(config)# interface ethernet 41
switch(config-if-Et41)# switchport mode tool
switch(config-if-Et41)# switchport tool truncation 160
switch(config-if-Et41)#

```

- These commands configure **interface ethernet 41** to send complete packets.

```
switch(config-if-Et41)# no switchport tool truncation
switch(config-if-Et41)#

```

## 21.1.4.5 Per-linecard TCAM Profile Configuration

This feature gives the ability to specify different profiles for different linecards in mixed mode.

To enable the TAP aggregation mode and configure a TCAM profile for a linecard set, complete the following steps:

1. Enable the switch for configuration.

```
switch> configure terminal

```

2. Enable TAP aggregation mode.

```
switch(config)# tap aggregation

```

### 3. Configure the TCAM profile for a linecard set.

```
switch(config-tap-agg) # mode mixed module linecard 3,4 profile tap-aggregation-default
switch(config-tap-agg) # mode mixed module linecard 5,6 profile tap-aggregation-extended
switch(config-tap-agg) #
```

To disable TAP aggregation on a linecard set, complete the following steps:

1. Enable the switch for configuration.

```
switch> configure terminal
```

2. Enable TAP aggregation mode.

```
switch(config)# tap aggregation
```

3. Disable TAP aggregation for a linecard set.

```
switch(config-tap-agg) # no mode mixed module linecard 3,4
switch(config-tap-agg) #
```

**Note:** If a TAP is a port-channel, its members must all come from linecards using the same profile.

#### 21.1.4.6 Two-Way Ports for TAP Aggregation

While in TAP aggregation mode, there is support for traffic only in one direction through either TAP ports that receive packets from mirroring, or through optical TAP or tool ports that send out packets to customer devices. Two-way ports for TAP aggregation allow bidirectional transmit and receive capability on a single port in TAP aggregation mode. Using the TAP-tool switchport mode enables both TAP and tool configurations simultaneously on an interface.

- [Two-Way Ports Platform Compatibility](#)
- [Two-Way Ports Configuration](#)

##### 21.1.4.6.1 Two-Way Ports Platform Compatibility

Two-way ports are available on selected platforms as described here: <https://www.arista.com/en/support/product-documentation/supported-features>.

##### 21.1.4.6.2 Two-Way Ports Configuration

To enable a two-way port, use the **tap-tool** option of the **switchport mode** command.

#### Example

The following commands configure **interface ethernet 4/1** as a two-way port, allowing it to function as both a TAP and a tool port.

```
switch(config)# interface ethernet 4/1
switch(config-if-Et4/1)# switchport mode tap-tool
switch(config-if-Et4/1) #
```

---

Additional configurations for TAP and tool functionality on the interface remain the same. Once the user enables the TAP-tool switchport mode on the interface, they can use the existing TAP and tool mode commands to enable their respective configurations.

Arista recommends using this feature with unidirectional send-receive enabled on the interface, which allows the receiver and transmitter for the interface to operate independently. If one goes down, the other remains active. To enable unidirectional send-receive on an interface, use the **unidirectional send-receive** command.

### Example

These commands enable unidirectional send-receive on **interface ethernet 4/1**.

```
switch(config)# interface ethernet 4/1
switch(config-if-Et4/1)# unidirectional send-receive
switch(config-if-Et4/1)#{/pre}
```

## 21.1.4.7 TAP Aggregation QoS Handling on TAP Ports

Before EOS 4.20.5F, QoS behavior was not enforced for TAP aggregation ports, meaning that QoS behavior for packets passing through the device was not changed.

- [QoS Handling Platform Compatibility](#)
- [QoS Handling Configuration](#)
- [Displaying QoS Handling Status](#)

### 21.1.4.7.1 QoS Handling Platform Compatibility

The following platforms support QoS handling on TAP ports.

- DCS-7280E
- DCS-7280R
- DCS-7500E
- DCS-7500R
- DCS-7280R2

**Note:** QoS is not available on TAP aggregation ports on the DCS-7150.

### 21.1.4.7.2 QoS Handling Configuration

#### Trust Mode of TAP Ports

TAP ports are in QoS **untrusted** mode by default. This means that the QoS marking of an incoming packet is not trusted when determining the QoS attributes of the packet. Therefore, the default QoS handling takes place. Consider the default CoS to traffic class mapping in the following example.

```
switch(config)# show qos maps
[...]
Cos-tc map:
cos: 0 1 2 3 4 5 6 7

tc: 1 0 2 3 4 5 6 7
[...]{/pre}
```

The Class of Service (CoS) field of incoming packets is ignored and is assumed to be zero. In this example, all packets are assigned to traffic class 1 when using the above mapping.

To override the default trust mode behavior on a TAP port, use the [qos trust](#) command.

### Example

The following commands override the default trust mode behavior on **Ethernet port 1**, configuring it to use Class of Service (CoS) trust mode instead so that incoming packets will be placed in their CoS-marked classes.

```
switch(config-if-Et1)# qos trust cos
switch(config-if-Et1)#{
```

### Class of Service Rewrite of TAP Ports

By default, TAP ports do not override the existing Class of Service (CoS) field of incoming packets. In other words, the CoS marking of steered packets is not changed in any way.

However, the CoS field of added tags may change according to the traffic class to CoS mapping. For example, the identity tag added by TAP ports may have the CoS value from the global traffic class to CoS mapping. Consider the following mapping:

```
switch(config)# show qos maps
[...]
 Tc-cos map:
 tc: 0 1 2 3 4 5 6 7

 cos: 1 7 2 3 4 5 6 0
[...]
```

Using this mapping, the added tag CoS field of packets assigned to **traffic class 1** may be set to **7**.

#### 21.1.4.7.3 Displaying QoS Handling Status

Use the [show qos maps](#) command to see the active QoS mappings.

### Example

This command displays the QoS maps that are configured on the switch.

```
switch# show qos maps
Number of Traffic Classes supported: 8
 Number of Transmit Queues supported: 8
 Cos Rewrite: Disabled
 Dscp Rewrite: Disabled

 Cos-tc map:
 cos: 0 1 2 3 4 5 6 7

 tc: 1 0 2 3 4 5 6 7

 Dscp-tc map:
 d1 : d2 0 1 2 3 4 5 6 7 8 9

 0 : 1 1 1 1 1 1 1 1 0 0
 1 : 0 0 0 0 0 0 2 2 2 2
 2 : 2 2 2 2 3 3 3 3 3 3
 3 : 3 3 4 4 4 4 4 4 4 4
 4 : 5 5 5 5 5 5 5 5 6 6
 5 : 6 6 6 6 6 6 7 7 7 7
 6 : 7 7 7 7 7 7 7 7 7 7

 Tc-cos map:
 tc: 0 1 2 3 4 5 6 7

```

```

cos: 1 0 2 3 4 5 6 7

Tc-dscp map:
 tc: 0 1 2 3 4 5 6 7

 dscp: 8 0 16 24 32 40 48 56

Tc - tx-queue map:
 tc: 0 1 2 3 4 5 6 7

 tx-queue: 0 1 2 3 4 5 6 7 switch#

```

## 21.1.4.8 Identity VLAN Tagging

By default, tool port output packets are identical to the replicated packets they receive from the tap ports to which they are associated. Identity tagging modifies packets sent by tool ports by adding a dot1q VLAN tag that identifies the originating TAP port. Each TAP port is associated with an identity number. Tool ports that are configured to add an identity tag append the originating TAP port's identity number in the outer layer (or s-VLAN) tag.

The following sections describe identity VLAN tagging on TAP and tool ports.

- [Tap Port Identity Value Configuration](#)
- [Tool Port Identity Tag Configuration](#)

### Tap Port Identity Value Configuration

The [switchport tap identity](#) command configures the TAP port identity value for the configuration-mode interface. The default identity value for all TAP ports is **1**.

#### Example

These commands configure **1042** as the identity value for **interface ethernet 42** and display the result.

```

switch(config)# interface ethernet 42
switch(config-if-Et42)# switchport tap identity 1042
switch(config-if-Et42)# show interface ethernet 41-43 tap
Port Configured Status Native Id Truncation Default
Mode Mode Vlan Vlan Vlan Group

Et41 tap tap 400 1 0 ---
Et42 tap tap 1 1042 0 ---
Et43 tap tap 1 1 0 ---
switch(config-if-Et42)#

```

### Tool Port Identity Tag Configuration

The [switchport tool identity](#) command configures the configuration-mode interface to include a tier-1 VLAN tag (dot1q) in packets it transmits. The VLAN number on the dot1q tag is the identity value configured for the TAP port that supplies the packets. By default, tool ports do not encapsulate packets with the tier-1 VLAN tag.

#### Example

These commands configure **port channel 102** to include the identity tag in packets it transmits.

```

switch(config)# interface port-channel 102
switch(config-if-Po102)# switchport tool identity dot1q
switch(config-if-Po102)# show interface port-channel 101-103 tool
Port Configured Status Allowed Id Timestamp
Mode Mode Vlans Vlans Tag Mode

Po101 tool tool 1001-1020 Off ---
Po102 tool tool 1010-1015 On ---
Po103 tool tool 1010-1030 Off ---

```

```
switch(config-if-Po102) #
```

#### 21.1.4.9 TAP Aggregation Group Configuration

TAP aggregation groups associate a set of TAP ports with a set of tool ports. A tool port replicates packets it receives from TAP ports that are in the aggregation groups to which it belongs. A TAP port can be configured to send data to multiple TAP aggregation groups. Tool ports may belong to multiple TAP aggregation groups. TAP aggregation groups may contain multiple TAP ports and multiple tool ports.

The following sections describe the configuration of TAP aggregation groups:

- [Assigning a Tool Port to a TAP Aggregation Group](#)
- [Assigning TAP Ports to a TAP Aggregation Group](#)
- [Viewing TAP Aggregation Group Assignments](#)
- [LAGs in Tool Groups](#)

#### Assigning a Tool Port to a TAP Aggregation Group

Tool ports are assigned to a TAP aggregation group through the [switchport tool group](#) command. Each command either creates a list or alters the existing list of groups to which a tool port belongs.

#### Examples

- These commands assign ***port-channel interface 101*** to TAP aggregation groups **analyze1**, **analyze2**, and **analyze3**.

```
switch(config)# interface port-channel 101
switch(config-if-Po101)# switchport tool group set analyze1 analyze2 analyze3
switch(config-if-Po101)# show active
interface Port-Channel101
 switchport mode tool
 switchport tap identity 2101
 switchport tool allowed vlan 1001-1020
 switchport tap default group tag-9
 switchport tool group set analyze3 analyze1 analyze2
switch(config-if-Po101) #
```

- These commands remove **analyze1** from ***port channel 101***'s TAP aggregation group list.

```
switch(config-if-Po101)# switchport tool group remove analyze1
switch(config-if-Po101)# show active
interface Port-Channel101
 switchport mode tool
 switchport tap identity 2101
 switchport tool allowed vlan 1001-1020
 switchport tap default group tag-9
 switchport tool group set analyze3 analyze2
switch(config-if-Po101) #
```

#### Assigning TAP Ports to a TAP Aggregation Group

TAP ports are assigned to a TAP aggregation group using the [switchport tap default group](#) command.

**Note:** A TAP port has multiple default groups.

Multiple ports can be added to a group simultaneously by entering the command in group interface configuration mode for all of the ports to be included.

#### Example

These commands assign **interface ethernet 41-42** to TAP aggregation group **analyze2** and assign **interface ethernet 43** to TAP aggregation group **analyze3**.

```
switch(config)# interface ethernet 41-42
switch(config-if-Et41-42)# switchport tap default group analyze2
switch(config-if-Et41-42)# interface ethernet 43
switch(config-if-Et43)# switchport tap default group analyze2
switch(config-if-Et43)# show interface ethernet 41-43 tap
Port Configured Status Native Id Truncation Default
 Mode Vlan Vlan Group

Et41 tap tap 400 1 0 analyze2
Et42 tap tap 1 1042 0 analyze2
Et43 tap tap 1 1 0 analyze3
switch(config-if-Et43)#

```

## Default TAP Aggregation Groups

A TAP port has multiple default groups. When traffic entering a TAP port does not match any filtering or traffic-steering rules for TAP aggregation groups configured on that port, it is sent to all default groups.

### Example

These commands assign **interface ethernet 43** to TAP aggregation groups **analyze2** and **analyze3**. Because it is listed first, **analyze2** is configured as the default group for the interface.

```
switch(config)# interface ethernet 43
switch(config-if-Et43)# switchport tap default group analyze2 group analyze3
switch(config-if-Et43)#

```

## Viewing TAP Aggregation Group Assignments

TAP aggregation group membership is displayed by [show tap aggregation groups](#). Options allow the display of individual groups or of all configured groups. The command displays active tool and TAP ports by default, and provides an option to display configured ports that are not active.

### Example

This command displays the contents of all configured TAP aggregation groups.

```
switch# show tap aggregation groups
Group Name Tool Members

analyze2 Po101, Po102
analyze3 Po101, Po103

Group Name Tap Members

analyze2 Et41, Et42
analyze3 Et43 switch#

```

## LAGs in Tool Groups

Link Aggregation Groups (LAGs) can be included in tool groups for load balancing. A tool group can contain both LAGs and regular ports. Each member of a tool group receives one copy of the traffic destined to the group. Traffic is replicated to tool group members using multicast replication. The traffic replicated to LAGs is then load balanced to their members as per load-balance policies configured on the system.

If a tool group has no more than **60** members with at least one hardware LAG, then the replication mode of the tool group is set to **ingress-only**. Otherwise, the replication mode of the tool group is set to the configured system default multicast replication mode. See [platform sand multicast replication default](#) for more information on configuration of the system default replication mode.

## Example

The following command changes the system-wide default multicast replication mode to **ingress**.

```
switch(config) # platform sand multicast replication default ingress
switch(config) #
```

## 21.1.5 TAP Aggregation Traffic Steering

Traffic steering is a TAP aggregation process that uses class maps and policy maps to direct data streams at tool ports that are not otherwise associated to the ingress TAP port. A policy map is a data structure that filters data streams upon which identity VLAN tagging or TAP aggregation group assignment is implemented.

TAP-aggregation class maps and policy maps are similar to QoS and control-plane maps. However, policy maps and their components are not interchangeable among function types.

### 21.1.5.1 TAP Aggregation Policies

A policy map filters data packets by using classes and match rules. Each class contains an eponymous class map and a traffic resolution command. Each match rule contains packet content descriptors and a traffic resolution parameter.

- A class map uses ACLs that identify packets that comprise a specified data stream.
- Packet content descriptors specify packet field values that are compared to inbound packets.
- A traffic resolution command or parameter specifies data handling methods for filtered traffic.

Each data packet entering an entity to which a policy map is assigned is managed as defined by the traffic resolution command of the highest priority class or rule that matches the packet.

Class maps are user-created and can be edited or deleted. They filter traffic with IPv4 ACLs and are listed in ***running-config***. TAP aggregation traffic resolution commands do one the following:

- specify a TAP aggregation group to direct the packet.
- specify a VLAN number for identity tagging the packet.

TAP aggregation policy maps do not define an implicit **deny** statement. Packets that do not match a policy map class or rule are replicated and sent out tool ports specified by the default aggregation group assigned to the ingress TAP port. If no default group is selected, these packets are dropped.

### 21.1.5.2 Configuring TAP Aggregation Traffic Policies

TAP aggregation traffic policies are implemented by creating class maps and policy maps, then applying the policy maps to Ethernet and port-channel interfaces.

#### Creating Class Maps

A class map is an ordered list of IPv4 Access Control Lists (ACLs). Each ACL is assigned a sequence number that specifies its priority in the class map. TAP aggregation class maps utilize ACL permit rules to pass packets and deny rules to drop packets.

Class maps are created and modified in class-map configuration mode, which is entered using the **class-map type tapagg**. The **match (class-map (tapagg))** command inserts a specified ACL into the class map, assigning it a sequence number that denotes its placement.

Class-map configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The **show active** command displays the saved version of class map. The **exit**

The **commit** command returns the switch to **global** configuration mode and saves pending class-map changes. The **abort** command returns the switch to global configuration mode and discards pending changes.

## Examples

- This command creates a TAP aggregation class map named **t-class\_1** and places the switch in the **class-map** configuration mode.

```
switch(config) # class-map type tapagg match-any t-class_1
switch(config-cmap-t-class 1) #
```

- These commands add two IPv4 ACLs (**tac1-1** and **tac1-2**) to the **t-class\_1** class map. The commands use the default method of assigning sequence numbers to the ACLs.

```
switch(config-cmap-t-class_1)# match ip access-group tac1-1
switch(config-cmap-t-class_1)#match ip access-group tac1-2
switch(config-cmap-t-class_1)#{
```

- These commands exit class-map configuration mode, store pending changes to ***running-config***, then display the class map.

```
switch(config-cmap-t-class_1)# exit
switch(config)# class-map type tapagg match-any t-class_1
switch(config-cmap-t-class_1)# show active
class-map type tapagg match-any t-class_1
10 match ip access-group tac1-1
20 match ip access-group tac1-2
switch(config-cmap-t-class_1)#

```

# Creating Policy Maps

Policy maps are created and modified in ***policy-map*** configuration mode. A policy map is an ordered list of classes and match rules. Policy maps are edited by adding or removing map elements. Data packets are managed by commands of the highest priority class or rule that matches the packet.

## Classes

Each class contains a class map, a set command, and a sequence number:

- The **class map** identifies a data stream by using an ordered list of ACLs. Class maps are configured in class-map (tapagg) configuration mode.
  - The **set** command specifies the replication method for filtered data packets, either through an associated aggregation group or identity VLAN tagging.
  - The **sequence number** specifies the class's priority within the policy map. Lower sequence numbers denote higher priority.

## Matching Rules

Each rule contains a filter list, an action, and a sequence number:

- The **filter list** identifies a data stream by using a set of packet field values.
  - The action, (**SET\_VALUE** parameter) specifies the replication method of filtered data packets, either through an associated aggregation group or identity VLAN tagging.
  - The **sequence number** specifies the rule's priority within the policy map. Lower sequence numbers denote higher priority.

**Policy-map** and **policy-map-class** configuration modes are group-change modes. Changes are saved with the **exit** command or discarded with the **abort** command. The **show active** and **show pending** commands display the saved and modified policy map versions respectively.

The **class (policy-map (tapagg))** command enters policy-map configuration mode.

## Example

This command creates the TAP aggregation policy map named ***t-policy\_1*** and places the switch in ***policy-map*** configuration mode.

```
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy 1)#

```

The **class** (*policy-map (tapagg)*) command adds a class to the configuration mode policy map and places the switch in ***policy-map-class*** configuration mode for adding a traffic resolution command to the class. The **set** (*policy-map-class (tapagg)*) command specifies the data replication method for traffic filtered by the associated class map in the *configuration-mode* policy map. The **set** command performs one of the following replication actions for filtered data packets.

- specifies an aggregation group.
  - specifies a VLAN identity tag for replicated packets.
  - specifies an aggregation group and a VLAN identity tag.

## Examples

- These commands add the **t-class\_1** class map to the **t-policy\_1** policy map, associate a set statement with the class, then save the policy map by exiting the modes. Packets filtered by the class map are identity tagged with **VLAN 444** and replicated as specified by the **t-grp** aggregation group.

```
switch(config-pmap-t-policy_1)# class t-class_1
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group
t-grp id-tag 444
switch(config-pmap-c-t-policy_1-t-class_1)# exit
switch(config-pmap-t-policy_1)# exit
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
10 class t-class_1
set aggregation-group t-group id-tag 444
switch(config-pmap-t-policy_1)#

```

The [match \(policy-map \(tapagg\)\)](#) command adds a match rule to the configuration-mode TAP aggregation policy map.

- This command enters policy-map configuration mode for ***t-policy\_1***, then creates a match rule for the policy map that filters OSPF packets and replicates them as specified by ***t-arp*** TAP aggregation group.

```
switch(config-pmap-t-policy_1)# match ip ospf any any set
aggregation-group t-grp
switch(config-pmap-t-policy 1)#

```

## Applying Policy Maps to an Interface

The [service-policy type tapagg \(Interface mode\)](#) command applies a specified policy map to the configuration-mode interface.

## Example

These commands apply the **t-policy\_1** policy map to **interface ethernet 17**.

```
switch(config)# interface ethernet 17
switch(config-if-Et17)# service-policy type tapagg input tpolicy_1
switch(config-if-Et17)#

```

## Stripping VLAN Tags

The traffic-steering policies in tap aggregation mode allows steering traffic from tap ports to tool ports using [set \(policy-map-class \(tapagg\)\)](#) command, while the 'set id-tag' tags the traffic with the specified VLAN ID in the dot1q format. The [class \(policy-map \(tapagg\)\)](#) command allows removing VLAN tags from the steered traffic. It supports all traffic types that the traffic steering policies support such as IPv4, IPv6, and MAC.

A tap port is an interface that receives a data stream where two network ports exchange.

A tool port is an interface that replicates data streams received by one or more tap ports. Tool ports connect to the devices that process monitored data streams.

### Example

These commands place the switch in policy-map-class to add the **t-class\_1** class map to the **t-policy\_1** policy map. The first, second, or both of the two outer-most VLAN tags are stripped.

```
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy 1)# class t-class_1
switch(config-pmap-t-policy_1-t-class_1)# set aggregation-group t-group remove dot1q outer 1-2
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group t-group id-tag 10
switch(config-pmap-c-t-policy_1-t-class_1)# set id-tag 10 remove dot1q outer 1
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group t-group
switch(config-pmap-c-t-policy_1-t-class_1)# set id-tag 10
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group t-group id-tag 10 remove dot1q
outer 1-2
```

### 21.1.5.3 Traffic Steering to Match Inner Header Fields

This feature allows matching the inner header fields (either IPv4 or IPv6 inner fields) of encapsulated traffic.

The following convention is adopted when describing an encapsulated traffic: **<inner-protocol>-over-<outer-protocol>**. For example, the IPv4-over-IPv6 packet indicates that the inner fields belong to IPv4 protocol and the outer fields belong to IPv6 protocol.

#### Supported Packet Types and Inner Header Fields

The types of traffic for which inner header field matching is supported are:

1. IP-over-IP traffic
2. IP-over-GRE traffic, with the following packet format supported:
  - [ Eth | IPv4 or IPv6 | GRE | Inner IPv4 or IPv6 ]
  - [ Eth | IPv4 | GRE | Inner Eth | Inner IPv4 ], which will be referred to as L2-GRE packet.
3. IP-over-GTP traffic (only in DCS-7280R3 and DCS-7500R3 series), with the following packet format supported
  - [ Eth | IPv4 | GTP | Inner IPv4 or IPv6 ]
  - [ Eth | IPv6 | GTP | Inner IPv4 or IPv6 ]

The following inner header fields are supported:

- inner source IP address.
- inner destination IP address.
- inner TCP/UDP protocol.
- inner source port number.
- inner destination port number.

### 21.1.5.3.1 Configuring Traffic Steering to Match Inner Header Fields

To enable traffic steering with an ACL rule that matches the inner IP addresses, a user-defined TCAM profile must be configured for each type of IP protocol to which the inner IP addresses belong. For example, to match the inner IPv4 addresses of an IPv4 packet (i.e. IPv4-over-IPv4 traffic) or the inner IPv4 addresses of an IPv6 packet (i.e. IPv4-over-IPv6 traffic), one user-defined TCAM profile must be configured. A different user-defined TCAM profile is needed if matching the inner IPv6 addresses of an IPv4 packet or the inner IPv6 addresses of an IPv6 packet is desired.

The following commands show how to configure different TCAM profiles needed to enable support for matching inner IP headers, depending on the desired inner IP version, and inner IP header fields to be matched. These TCAM profiles are referred to as user-defined TCAM profiles and created based on the existing TCAM profile tap-aggregation-extended.

#### TCAM Profile to Match Inner IPv4 Header Fields

##### Match inner IPv4 addresses only.

The following commands configure the TCAM profile for matching only the inner source and destination IP addresses of IPv4 traffic based on the existing TCAM profile **tap-aggregation-extended**.

##### Example

```
switch(config)# hardware tcam
switch(config-hw-tcam)# profile tap-aggregation-user-inner-ip4 copy tap-aggregation-extended
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# no key field src-ip dst-ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# key field inner-src-ip-high inner-src-ip-low inner-dst-ip-high inner-dst-ip-low
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# feature tapagg ipv6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ipv6)# no key field src-ipv6 src-ipv6-high dst-ipv6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ipv6)# key field inner-src-ip-high inner-src-ip-low inner-dst-ip-high inner-dst-ip-low
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ipv6)# exit
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# exit
```

##### Match inner IPv4 addresses, inner TCP/UDP protocol and inner port numbers for IP-over-IP and IP-over-GRE traffic.

In addition to matching inner IPv4 addresses, the previous user-defined TCAM profile can also be configured to match the inner TCP/UDP protocol and their corresponding port numbers. The commands to configure these inner fields are shown below.

Note that, due to hardware limitation, the feature “tapagg mac” is disabled in this TCAM profile to make room for matching additional inner header fields.

##### Example

```
switch(config-hw-tcam)# profile tap-aggregation-user-inner-ip4
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# no feature tapagg mac
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# no key field outer-vlan-id inner-vlan-id 14-src-port 14-dst-port udf-16b-1 udf-16b-2 udf-16b-3 udf-16b-4
udf-32b-1 udf-32b-2
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# key field inner-ip-protocol inner-14-src-port inner-14-dst-port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# feature tapagg ipv6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ipv6)# no key field 14-src-port 14-dst-port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ipv6)# key field inner-ip-protocol inner-14-src-port inner-14-dst-port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ipv6)# exit
```

```
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# exit
```

### Match inner IPv4 addresses, inner TCP/UDP protocol and inner port numbers for L2-GRE packets.

The same user-defined TCAM profile can be updated to support traffic steering that matches on inner header fields for L2-GRE packets, simply by adding a new packet type.

#### Example

```
switch(config-hw-tcam)# profile tap-aggregation-user-inner-ip4
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# packet ipv4 eth
 ipv4 forwarding bridged
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# feature tapagg port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-port)# packet ipv4 eth
 ipv4 forwarding bridged
```

### Match inner IPv4 addresses, inner TCP/UDP protocol and inner port numbers for IP-over-GTP packets.

We can re-use the same user-defined TCAM profile and update it to support traffic steering that matches on inner header fields for IP-over-GTP packets, simply by adding a new packet type.

#### Example

```
switch(config-hw-tcam)# profile tap-aggregation-user-inner-ip4
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# no packet ipv4
 eth ipv4 forwarding bridged
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-ip)# packet ipv4 gtpv1
 ipv4 forwarding bridged
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# feature tapagg port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-port)# no packet ipv4
 eth ipv4 forwarding bridged
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-port)# packet ipv4
 gtpv1 ipv4 forwarding bridged
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4)# feature tapagg ipv6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip4-feature-tapagg-port)# packet ipv6
 gtpv1 ipv4 forwarding bridged
```

### Match inner and outer IPv4 addresses.

If matching a combination of inner and outer IP header fields is desired, the user-defined TCAM profile must be updated to include the desired fields. For example, instead of matching both inner source and inner destination IPv4 addresses as illustrated by this TCAM profile, if users would like to match outer source IPv4 address and inner destination IPv4 address only (and ignoring outer destination and inner source IPv4 addresses). The following commands show how to configure a TCAM profile for such filtering.

#### Example

```
switch(config)# hardware tcam
switch(config-hw-tcam)# profile tap-aggregation-user-outer-inner-ip4 copy tap-aggregation-extended
switch(config-hw-tcam-profile-tap-aggregation-user-outer-inner-ip4)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-outer-inner-ip4-feature-tapagg-ip)# no key
 field dst-ip
switch(config-hw-tcam-profile-tap-aggregation-user-outer-inner-ip4-feature-tapagg-ip)# key field
 inner-src-ip-high inner-src-ip-low
switch(config-hw-tcam-profile-tap-aggregation-user-outer-inner-ip4-feature-tapagg-ip)# exit
switch(config-hw-tcam-profile-tap-aggregation-user-outer-inner-ip4)# exit
```

### TCAM Profile to Match Inner IPv6 Header Fields

#### Match inner IPv6 addresses only.

These commands are to configure a TCAM profile that can match inner IP addresses of IPv6 traffic are as follows:

### Example

```
switch(config)# hardware tcam
switch(config-hw-tcam)# profile tap-aggregation-user-inner-ip6 copy tap-aggregation-extended
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ip)# no key field dst-
ip src-ip udf-16b-1 udf-16b-2 udf-16b-3 udf-16b-4 udf-32b-1 udf-32b-2 outer-vlan-id inner-vlan-id
14-src-port 14-dst-port 14-ops
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ip)# key field inner-
src-ipv6-high-high-32b inner-src-ipv6-high-low-32b inner-src-ipv6-low-high-32b inner-src-ipv6-low-
low-32b
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ip)# key field inner-
dst-ipv6-high-high-32b inner-dst-ipv6-high-low-32b inner-dst-ipv6-low-high-32b inner-dst-ipv6-low-
low-32b
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ip)# exit
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# feature tapagg ipv6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ipv6)# no key field
src-ipv6 src-ipv6-high dst-ipv6 14-dst-port 14-src-port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ipv6)# key field
inner-src-ipv6-high-high-32b inner-src-ipv6-high-low-32b inner-src-ipv6-low-high-32b inner-src-
ipv6-low-low-32b
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ipv6)# key field
inner-dst-ipv6-high-high-32b inner-dst-ipv6-high-low-32b inner-dst-ipv6-low-high-32b inner-dst-
ipv6-low-low-32b
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ipv6)# exit
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# exit
```

### Match inner IPv6 addresses, inner TCP/UDP protocol and inner port numbers.

In addition to matching inner IPv6 addresses, the previous user-defined TCAM profile can also be configured to match the inner TCP/UDP protocol and their corresponding port numbers. The commands to configure these inner fields are shown below.

Note that, due to hardware limitation, the feature **tapagg mac** is disabled in this TCAM profile to make room for matching additional inner header fields.

### Example

```
switch(config-hw-tcam)# profile tap-aggregation-user-inner-ip6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# no feature tapagg mac
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ip)# key field inner-
ipv6-next-header inner-14-src-port inner-14-dst-port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ip)# feature tapagg
ipv6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ipv6)# key field
inner-ipv6-next-header inner-14-src-port inner-14-dst-port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ipv6)# exit
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# exit
```

### Match inner IPv6 addresses, inner TCP/UDP protocol and inner port numbers for IP-over-GTP packets.

We can re-use the same user-defined TCAM profile and update it to support traffic steering that matches on inner header fields for IP-over-GTP packets, simply by adding a new packet type.

```
switch(config-hw-tcam)# profile tap-aggregation-user-inner-ip6
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# feature tapagg ip
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-ip)# packet ipv4 gtpv1
ipv6 forwarding bridged
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# feature tapagg port
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-port)# packet ipv4
gtpv1 ipv6 forwarding bridged
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6)# feature tapagg ipv6
```

```
switch(config-hw-tcam-profile-tap-aggregation-user-inner-ip6-feature-tapagg-port)# packet ipv6
gtpv1 ipv6 forwarding bridged
```

## Apply TCAM Profile

To apply the newly-defined TCAM profile use **tap-aggregation-user-inner-ip4** or **tap-aggregation-user-inner-ip6** command.

```
switch(config)# tap aggregation
switch(config-tap-agg)# mode exclusive profile tap-aggregation-user-inner-ip4
```

For modular systems

```
switch(config)# tap aggregation
switch(config-tap-agg)# mode mixed module Linecard <linecard number> profile tap-aggregation-user-inner-ip4
```

## Set-Up ACL Rules for Matching Inner Header Fields

In order to apply traffic steering for particular packets based on their inner header fields, ACL rules that can filter such traffic must be created, as shown in the example.

1. ACL rule for filtering an IPv4-over-IPv4 traffic based on the inner addresses.

```
switch(config)# ip access-list acl1
switch(config-acl-acl1)# permit ip any any inner ip host 1.2.3.4 host 5.6.7.8
```

2. ACL rule for filtering an IPv4-over-IPv4 traffic based on the outer source and inner destination addresses.

```
switch(config)# ip access-list acl1
switch(config-acl-acl1)# permit ip host 1.2.3.4 any inner ip host any host 5.6.7.8
```

3. ACL rule for filtering an IPv6-over-IPv4 traffic based on the inner addresses.

```
switch(config)# ip access-list acl2
switch(config-acl-acl2)# permit ip any any inner ipv6 host 1001::abcd host 2002::cafe
```

4. ACL rule for filtering an IPv4-over-IPv6 traffic based on the inner addresses, inner TCP/UDP protocol, and inner TCP/UDP ports.

```
switch(config)# ipv6 access-list acl3
switch(config-ipv6-acl-acl3)# permit ipv6 any any inner ip tcp host 10.11.12.13 eq 9999 host 20.22.24.26 eq 8888
```

5. ACL rule for filtering an IPv6-over-GRE(IPv4) traffic based on the inner addresses, inner TCP/UDP protocol, and inner TCP/UDP ports.

```
switch(config)# ip access-list acl4
switch(config-acl-acl4)# permit gre any any inner ipv6 udp host 2019::baba eq 9999 host 1986::deca eq 8888
```

6. ACL rule for filtering an IPv4-over-GTP traffic based on the inner addresses.

```
switch(config)# ip access-list acl5
switch(config-acl-acl5)# permit gtp any any version 1 protocol gtp-u inner ip host 1.2.3.4 host 5.6.7.8
```

### 21.1.5.3.2 Limitations

- Only IP (IPv4 and IPv6), GRE and GTP outer protocols are supported.
  - Other outer protocols are not supported.
- Only IP (IPv4 and IPv6), TCP and UDP inner protocols are supported.
  - Other inner protocols are not supported.
- To configure support for matching inner IPv4 addresses (for either IPv4 or IPv6 outer packets), a custom user-defined TCAM profile is required. A different user-defined TCAM profile is needed if matching inner IPv6 addresses is desired.
- The total size of fields to match must not exceed the TCAM key size limitation (which is **320** bit if tap-aggregation-extended system profile is used as the base profile, or **160** bit for tap-aggregation-default system profile). For example, it is not possible to create a user-defined TCAM profile that matches both outer and inner source/destination address pairs for an IPv6-over-IPv6 packet. This is because each IPv6 address is **128** bit, requiring at least **512** bit to match all **4** addresses, and the TCAM key size is limited to **320** bit.

## 21.1.6 TAP Aggregation GUI

The switch provides a Graphical User Interface (GUI) for creating and viewing a TAP aggregation configuration and displaying LANZ traffic statistics.

All commands available on the GUI are accessible through the CLI. The TAP aggregation configuration created through either the CLI or the GUI can be viewed and modified through either medium.

This section provides a brief description of the TAP aggregation GUI.

### 21.1.6.1 Accessing the TAP Aggregation GUI

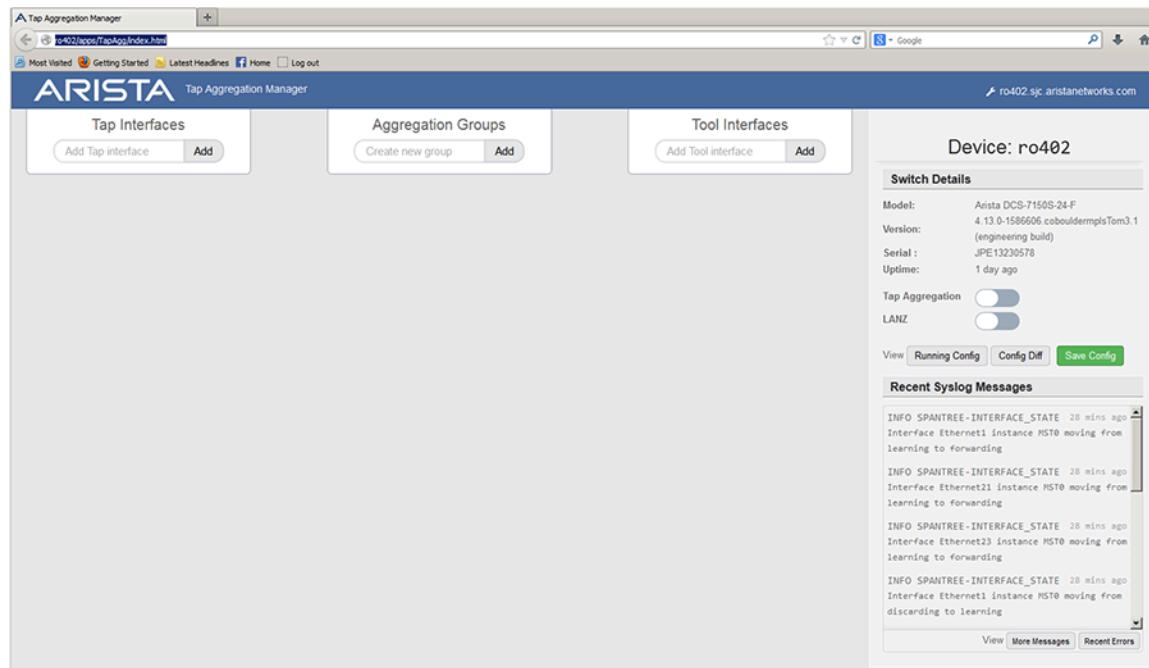

The URL for the TAP aggregation GUI is: `//hostname/apps/TapAgg/index.html` where the hostname is the switch's configured hostname. The **TAP Aggregation GUI Initial Panel** displays the initial TAP aggregation GUI panel for the switch with the hostname **ro402**.

The TAP aggregation panel contains two sections:

- The **configuration section** displays the TAP aggregation configuration, including the TAP interfaces, tool interfaces, and aggregation groups. Links are displayed to indicate interface group membership.
- The **component section** displays information and control buttons for the active configuration entity. When an entity is not selected, the section displays information for the switch (device).

The configuration section displays TAP aggregation components only when the switch is in TAP aggregation mode. To enter TAP aggregation mode, click the TAP Aggregation icon in the component section for the device. The icon is a toggle mechanism; clicking it again disables TAP aggregation mode.

**Figure 21-1: TAP Aggregation GUI Initial Panel**

### 21.1.6.2 Viewing TAP Aggregation Component Details

[TAP Aggregation GUI Panel with TAP Aggregation Mode Enabled](#) displays the TAP aggregation panel when the switch is in TAP aggregation mode. The configuration section indicates that the TAP aggregation configuration consists of three tool interfaces, one TAP interface, and four aggregation groups. **Ethernet port 10** is the active component; configuration control and traffic information for this interface is available in the component section.

The active component is changed by clicking on the desired component in the configuration section. To display device (switch) information, click on any configuration section outside of any component.

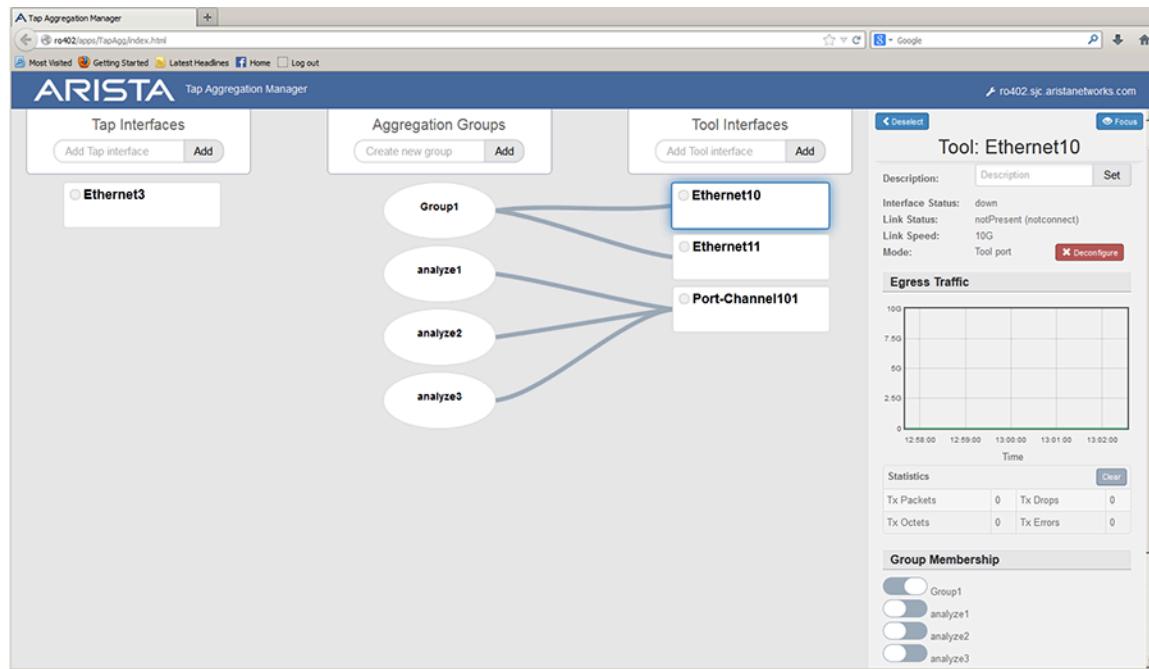

### 21.1.6.3 Modifying a TAP Aggregation Configuration

The TAP aggregation configuration can be modified only when the switch is in TAP aggregation mode, (see [Accessing the TAP Aggregation GUI](#)). The following is a partial list of configuration tasks that are available from the GUI:

- **adding a TAP or tool interface:** begin typing the interface name in the desired add-interface data entry area to access a drop-down list of available interfaces. Select the desired interface and press the **Add** button.
- **removing an interface from the configuration:** select the desired interface in the configuration section and click the deconfigure button in that interface's component section.
- **adding an aggregation group:** type the desired name of the new group in the data entry area and press the **Add** button. The TAP aggregation group name can consist of alphanumeric characters and specific special characters (- \_ [ ] { } :) only.
- **adding an interface to an aggregation group:** select the desired interface in the configuration section, then press the icon of the group in the group membership area of the interface's component section.

Group icons are toggle buttons; clicking the icon of a group to which the interface belongs removes that interface from the group.

**Figure 21-2: TAP Aggregation GUI Panel with TAP Aggregation Mode Enabled**

## 21.1.7 TAP Aggregation Keyframe and Timestamp Configuration

This section contains the following topics:

- [TAP Aggregation Keyframe Generation](#)
- [Enabling Timestamp Insertion on an Interface](#)

### 21.1.7.1 TAP Aggregation Keyframe Generation

Keyframes contain routable IP packets that provide information to relate timestamps with the complete ASIC counter and absolute UTC time. The switch supports a maximum of ten keyframes, which are distinguished by their name label. Each keyframe can egress from every Ethernet port.

Keyframe generation is enabled by the [platform fm6000 keyframe](#) command. Command options specify ports that transmit keyframes along with the destination MAC address and IP address in the keyframe's header. Other keyframe commands specify the transmission rate and the frame's source:

- the [platform fm6000 keyframe rate](#) command configures the keyframe's transmission rate.
- the [platform fm6000 keyframe source](#) command configures the source IP address that is placed in each keyframe's header. The management interface IP address is the default source address.

The source MAC address is the MAC address of the egress interface transmitting the keyframe

- the [platform fm6000 keyframe device](#) command configures the 16-bit number that keyframes list as the device ID in their payload.
- the [platform fm6000 keyframe fields skew](#) command enables the inclusion of clock skew fields in the keyframe.

- the `show platform fm6000 keyframe` command displays keyframe configuration information.

### Examples

- This command enables the generation of a keyframe named **key-1** and configures it to egress from interfaces ethernet **11** through **15** with a source IP address of **10.21.1.4** and a MAC address of **10.4E21.9F11**.

```
switch(config)# platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4
10.4E21.9F11
switch(config) #
```

- This command configures the generation rate for the keyframe of **10** frames per second on each of the five interfaces that it is configured to egress.

```
switch(config)# platform fm6000 keyframe key-1 rate 10
switch(config) #
```

- This command enables the generation of a keyframe named **key-1** and configures **100** as the value that is placed in the keyframe's device ID field.

```
switch(config)# platform fm6000 keyframe key-1 device 100
switch(config) #
```

- This command enables the inclusion of clock skew fields in the keyframe named **key-1**.

```
switch(config)# platform fm6000 keyframe key-1 fields skew
switch(config) #
```

- This command displays configuration information for keyframe **key-1**.

```
switch(config)# show platform fm6000 keyframe

Keyframe key-1

Egress Interface(s): Ethernet11, Ethernet12, Ethernet13, Ethernet14, Ethernet15
Source IP: 172.22.30.142
Destination IP: 10.21.1.4
Destination MAC: 00:10:4e:21:9f:11
Device ID: 100
Rate: 10 packet(s) per second

switch(config) #
```

### 21.1.7.2 Enabling Timestamp Insertion on an Interface

EOS bases timestamps on a frame's ingress time and applies them to frames sent on egress ports, ensuring that timestamps on monitored traffic reflect ingress timing of the original frames. Time-stamping is configured on the egress port where the timestamp is applied to the frame.

When timestamping is enabled on an egress interface, packets leave the interface with timestamps that were applied in hardware when the packet arrived at the switch. This is facilitated by applying a hardware timestamp to all frames arriving on all interfaces when timestamping is enabled on any interface, then removing timestamps on packets egressing interfaces where timestamping is not enabled.

The `mac timestamp` command enables time-stamping on the configuration-mode interface. The 7150 switch supports two timestamp modes, which differ in managing the egress frame's 32-bit Frame Check Sequence (FCS):

- **before-fcs:** the switch discards the original FCS, appends the ingress timestamp at the end of the frame data, recalculates a new FCS based on the appended timestamp, then appends the new FCS to the end of the frame. This creates a valid Ethernet frame but does not update headers of any nested protocols.
- **replace-fcs:** the switch replaces the original FCS with the timestamp. This mode maintains the size of the original frame without any latency impact, but the FCS is not valid.

**Note:** The timestamp insertion method varies by platform. See [An Overview of Arista Ethernet Capture Timestamps](#) for more information about the differences for each platform.

## Examples

- These commands enable timestamping in **before-fcs** mode on **interface ethernet 44** on a 7150 platform.

```
switch(config)# interface ethernet 44
switch(config-if-Et44)# mac timestamp before-fcs
switch(config-if-Et44)# show active
interface Ethernet44
 mac timestamp before-fcs
switch(config-if-Et44)#[/pre]

```

- These commands disable timestamping on **interface ethernet 44** on a 7150 platform..

```
switch(config-if-Et44)# no mac timestamp
switch(config-if-Et44)# show active
interface Ethernet44
switch(config-if-Et44)#[/pre]

```

## 21.1.8 TapAgg GRE Tunnel Termination

The TapAgg GRE Tunnel Termination feature terminates the GRE packets on a TapAgg switch by stripping the GRE header and then letting the decapped packets go through the normal TapAgg path. With this feature, we can use an L3 GRE tunnel to transit tapped traffic to the TapAgg switch over an L3 network. That would widely extend the available use cases for TapAgg.

- Support IPv4 GRE tunnel interfaces only.
- Support the following GRE types: IPoGRE, L2GRE, GReenSPAN, ERSPAN Type I, ERSPAN Type II, and GReenTAP.
- Do packet forwarding/steering on the decapped packets. Not routing.
- Packets can be forwarded to a set of tool ports.
- Have a command to configure for not stripping the GRE header, so that the TapAgg side may use the information present in the GRE metadata.

### 21.1.8.1 Configuring TapAgg GRE Tunnel Termination

The TapAgg GRE Tunnel Termination is allowed to be configured in the following two modes:

- TapAgg Exclusive Mode
- TapAgg Mixed Mode

### 21.1.8.1.1 TapAgg Exclusive Mode

In Tapagg Exclusive mode, GRE tunnel termination is enabled on a selected tap ports through CLI. When traffic comes into those tap ports, the matched GRE packets are decapped and forwarded to the tap port's default forwarding destinations or the steering destinations if it matches the policy ACLs applied.

#### Adding the TCAM Feature

Tap tunnel termination on tapAgg exclusive mode is supported by built-in profiles **tap-aggregation-default** and **tap-aggregation-extended**. Custom profiles can support tap tunnel termination with the configuration of the tapagg tunnel termination feature through the following steps:

```
switch# configure
switch(config)# hardware tcam
switch(config-tcam)# profile tap-aggregation-gre copy tap-aggregation-profile
switch(config-tcam-profile-tap-aggregation-gre)# feature tapagg tunnel termination copy system-
feature-source-profile
switch(config-tcam-feature-tapagg-tunnel-termination)# exit
switch(config-tcam-profile-tap-aggregation-gre)# exit
Saving new profile 'tap-aggregation-gre'
switch(config-tcam)# exit
switch(config)#
```

To check if a TCAM profile has the feature, use the following command:

```
switch(config)# show hardware tcam profile tap-aggregation-gre
Features enabled in TCAM profile tap-aggregation-gre:
mpls
acl port ipv6
tapagg port
tapagg mac
tapagg ip
tapagg ipv6
tapagg tunnel termination
acl port ip
tunnel VXLAN
acl port mac
forwarding-destination mpls
```

#### Change Hardware Forwarding Profile

On DCS-7280R3, DCS-7500R3 and DCS-7800R3 systems, the hardware forwarding profile needs to be set to **system-profile-tap-aggregation** on all linecards.

#### Enable GRE Termination on a Tap Port

Use **switchport tap encapsulation gre [tunnel destination <dst IP address> [source <src IP address> ]] strip** to enable GRE termination on a tap port. The command allows specification of tunnel endpoints, to support termination on a specific tunnel.

```
switch(config-if-Et7/1)# switchport tap encapsulation gre destination <dst-ip> source <src-ip>
strip
```

Without the specification of tunnel endpoints, it will terminate GRE packets for all tunnels. If only the destination endpoint is specified, then any GRE packet that matches this destination is terminated.

#### Example

In this example the following configuration tap port **et7/1** will strip GRE packets for all GRE tunnels and forward the decapped packets to tool group **tool1**.

```
switch(config-if-Et7/1)# switchport mode tap
switch(config-if-Et7/1)# switchport tap default group tool1
```

```
switch(config-if-Et7/1) # switchport tap encapsulation gre strip
```

## GRE Termination into Traffic Steering

If the matched GRE packet also hits the policy map that is applied on the tap port, after stripping the GRE header, the packets are forwarded to the steering destination configured for the policy map. In the example below, a policy map named 'pm' is applied on the tap port which has gre strip enabled on it. Then the GRE packets with an outer destination IP **dst-ip** and source IP **src-ip**, matching the permit rule in the policy map, is forwarded to the tool group **tool2** after stripping the GRE header.

**Note:** The ACLs are applied on the original GRE packet, and not the one after the GRE header is stripped.

```
switch(config)# show policy-map type tapagg
Service policy pm
 Configured on:
 Applied on:
 10: Class-map: cm (match-any)
 Match: 10 IP Access List testAcl
 10 permit ip host 1.1.1.1 host 2.2.2.2

 Configured actions: set group tool2

switch(config-if-Et7/1)#show active
interface Ethernet7/1
 service-policy type tapagg input pm
 switchport mode tap
 switchport tap encapsulation gre strip
 switchport tap default group tool1
```

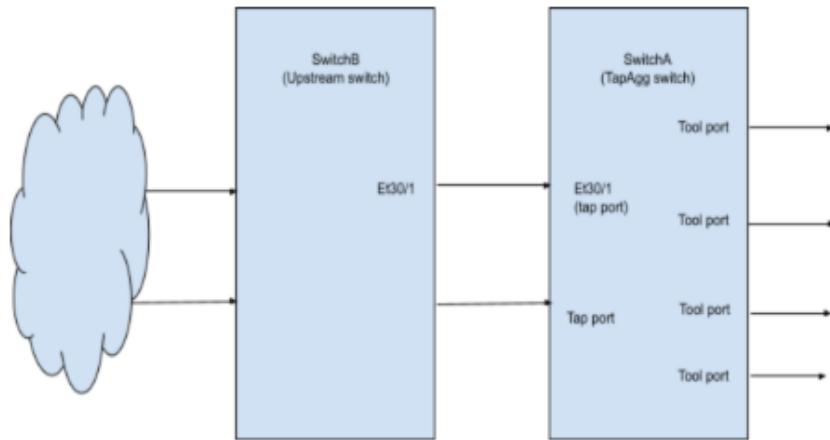

## GRE Termination with Ingress/Egress Truncation

When there is truncation enabled, either on the tap port that has GRE termination configured or on the tool port that is configured to egress out the decapped packets, the GRE header is stripped from the truncated packets. In other words, the GRE header stripping occurs after truncation. That means the size of the egress packet will be less than the original expectation. For example, if we have configured to truncate packets to a size of **178** bytes, after enabling GRE termination, the egress out packet for a GReenSpan will have a size of **136**. It is **178** minus **42** (the total bytes stripped for GReenSpan).

## Configuring the Upstream Switch

In TapAgg exclusive mode, the routing protocols are not running so TapAgg Switch will rely on its upstream switch which has routing protocol enabled to forward the GRE packets to it. Tap ports which are selected to receive the GRE packets should be connected to the upstream switch. The upstream switch needs to configure a static route to forward the GRE packets to the link.

## Example

If TapAgg switch A is connected to the upstream **Switch B** through the link between **A-et30/1** and **B-et30/1** then the static route for forwarding GRE packets with Destination IP address **40.1.1.2** terminated on TapAgg **Switch A** can be configured with the following commands:

```
switchB(config-if-Et30/1) # show active
interface Ethernet30/1
 speed forced 100gfull
 no switchport
 ip address 10.10.10.1/24
SwitchB(config-if-Et30/1) # ip route 40.1.1.2/32 ethernet 30/1
```

The static route should be present in the output of the **show ip route** command.

```
switchB# show ip route

VRF: default
Codes: C - connected, S - static, K - kernel,
 O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
 E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
 N2 - OSPF NSSA external type2, B - BGP, B I - iBGP, B E - eBGP,
 R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
 O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
 NG - Nexthop Group Static Route, V - VXLAN Control Service,
 DH - DHCP client installed default route, M - Martian,
 DP - Dynamic Policy Route, L - VRF Leaked,
 RC - Route Cache Route

Gateway of last resort is not set

C 10.10.10.0/24 is directly connected, Ethernet30/1
S 10.80.0.0/13 [1/0] via 10.240.25.1, Management1
S 10.95.0.0/16 [1/0] via 10.240.25.1, Management1
C 10.240.25.0/25 is directly connected, Management1
S 10.240.0.0/15 [1/0] via 10.240.25.1, Management1
S 10.242.0.0/15 [1/0] via 10.240.25.1, Management1
S 40.1.1.2/32 is directly connected, Ethernet30/1
S 172.16.0.0/12 [1/0] via 10.240.25.1, Management1
```

Setup static ARP entry for the route. **44:4c:a8:be:35:e9** is the MAC address of **A-et30/1**. Note that any unicast MAC address can be used for static ARP entry.

```
switchB(config) # arp 40.1.1.2 44:4c:a8:be:35:e9 arpa
```

Use the following command to check ARP entries.

```
switchB# show arp
Address HWtype HWaddress Flags Mask Iface
10.240.25.1 ether 28:99:3a:67:7f:93 C 00:0c:0e:00:00:00 m1
40.1.1.2 ether 44:4c:a8:be:35:e9 CM 00:0c:0e:00:00:00 et30_1
```

With the above configurations, the upstream **Switch B** can forward the GRE packets to TapAgg **Switch A**.

#### 21.1.8.1.2 TapAgg Mixed Mode

For a modular system, such as the DCS-7500R or DCS-7500R2, routed ports on a non-TapAgg linecard is used to receive GRE packets. In order to use the tap tunnel termination feature, **dbTapTunnelTermination** must be added to the TCAM profile for the non-TapAgg linecards.

##### Adding the TCAM Feature

For example, if the current system profile is profile **default**, we can use the following commands to create a new profile **default-with-tap-gre**, which is copied from the current system profile, and add the new feature that we need.

```
switch(config)# hardware tcam
switch(config-tcam)# profile default-with-tap-gre copy default
switch(config-tcam-profile-default-with-tap-gre)# feature tapagg tunnel termination copy system-
feature-source-profile
switch(config-tcam-feature-tapagg-tunnel-termination)# exit
switch(config-tcam-profile-default-with-tap-gre)# exit
Saving new profile 'default-with-tap-gre'
switch(config-tcam)# exit
```

Use the following command to apply the new TCAM profile.

```
switch(config)# hardware tcam
switch(config-tcam)# system profile default-with-tap-gre
```

Configure TapAgg mixed mode. In the below example, we configure TapAgg mixed mode and leave the linecard **6** in normal mode.

```
switch(config)# tap agg
switch(config-tap-agg)# mode mixed module linecard 3,4,5
! Changing modes may affect available functionality. Unsupported configuration elements will be
ignored.
switch(config)#show hardware tcam profile
 Configuration Status
Linecard3 tap-aggregation-default* tap-aggregation-default
Linecard4 tap-aggregation-default* tap-aggregation-default
Linecard5 tap-aggregation-default* tap-aggregation-default
Linecard6 default-with-tap-gre default-with-tap-gre
* configuration overridden by TapAgg
```

There could be some cases where we need to remove some features from the TCAM profile in order to have room to fit the feature **tapagg tunnel termination** in. This kind of ‘tradeoff’ is needed when we want this feature to be with a specific user-defined tcam profile.

Below is an example of solving that problem.

```
switch(config)# tap agg
switch(config-tap-agg)# mode mixed module linecard 3,4,5
! Changing modes may affect available functionality. Unsupported configuration elements will be
ignored.
switch(config)# show hardware tcam profile
 Configuration Status
Linecard3 tap-aggregation-default* tap-aggregation-default
Linecard4 tap-aggregation-default* tap-aggregation-default
```

```

Linecard5 tap-aggregation-default* tap-aggregation-default
Linecard6 default-with-tap-gre ERROR
* configuration overridden by TapAgg

switch(config)# hardware tcam
switch(config-tcam)# profile default-with-tap-gre
switch(config-tcam-profile-default-with-tap-gre)# no feature mirror ip
switch(config-tcam-profile-default-with-tap-gre)# no feature pbr ip
switch(config-tcam-profile-default-with-tap-gre)# exit
switch(config-tcam)# show hardware tcam profile
 Configuration Status
Linecard3 tap-aggregation-default* tap-aggregation-default
Linecard4 tap-aggregation-default* tap-aggregation-default
Linecard5 tap-aggregation-default* tap-aggregation-default
Linecard6 default-with-tap-gre default-with-tap-gre
* configuration overridden by TapAgg

```

## Change Hardware Forwarding Profile

On DCS-7280R3, DCS-7500R3 and DCS-7800R3 systems, the hardware forwarding profile needs to be set to system-profile-tap-aggregation on all tap agg linecards. Detailed instructions on how to set it can be found in the Resources section.

## Configure GRE Tunnel Interface

Configure the GRE tunnel interface that we want the packets it received to be terminated and redirected.

In the below example, the GRE packets for this tunnel interface should have destination IP address **40.1.1.1** and source IP address **40.1.1.2**.

```

switch(config)# interface tunnel 1
switch(config-if-Tu1)# tunnel mode gre
switch(config-if-Tu1)# tunnel source 40.1.1.1
switch(config-if-Tu1)# tunnel destination 40.1.1.2

```

For a tunnel interface, if **tunnel source** is configured but **tunnel destination** is not, then any GRE packet with destination IP address matching the tunnel source will be stripped and redirected. In the example below, the GRE packet with destination IP **40.1.1.1** is what we are interested in.

```

switch(config-if-Tu1)# show active
 tunnel mode gre
 tunnel source 40.1.1.1
 tap default group gr1
 tap default interface Ethernet3/1

```

If neither **tunnel source** nor **tunnel destination** is configured, then the GRE packets for any endpoints will be stripped and redirected.

```

switch(config-if-Tu1)# show active
 tunnel mode gre
 tap default group gr1
 tap default interface Ethernet3/1

```

Use the **tap default group** and **tap default interface** commands to configure the redirecting destination. In the example below, the GRE packets sent to **interface tunnel 1** will be redirected to tool group gr1 and tool **interface et3/1** after stripping the GRE header. (In current version, the target interfaces must be tool ports on TapAgg linecards. A non tool port putting in this command will not take effect.)

```

switch(config)# interface tunnel 1
switch(config-if-Tu1)# tap default group gr1
switch(config-if-Tu1)# tap default interface ethernet 3/1
switch(config-if-Tu1)#

```

If we want to redirect the packets but do not want to strip the GRE header, command **tap encapsulation gre preserve** can be configured for that purpose, not stripping the GRE header.

```
switch(config)# interface tunnel 1
switch(config-if-Tu1)# tap encapsulation gre preserve
switch(config-if-Tu1)#{/pre}

```

The show command below is used to check the tunnel interface status. In TapAgg mixed mode, routing protocols can run on non-TapAgg linecards, and any routed port in non-TapAgg linecards can be used to receive the GRE packets. For Tap tunnel termination feature, the status of the tunnel interface doesn't have to be **connected**, but there must be some routes to help the GRE packets find the way to the routed ports on this switch.

```
switch(config)# show interfaces tunnel 1
Tunnel1 is up, line protocol is up (connected)
 Hardware is Tunnel, address is 2801.0102.0800
 Tunnel source 40.1.1.2, destination 40.1.1.1
 Tunnel protocol/transport GRE/IP
 Hardware forwarding enabled
 Tunnel transport MTU 1476 bytes (default)
 Up 35 minutes, 57 seconds{/pre}

```

### Enable Tap Tunnel Termination on TapAgg Linecards in Mixed Mode

If you do want to enable GRE Termination on a specific tap port in TapAgg mixed mode, follow the **TapAgg exclusive mode** section and refer to configuring TCAM profile and GRE termination for the TapAgg linecard.

## 21.1.9 Tap Aggregation Hardware Forwarding Profile

In order to enable the MPLS Pop and 802.1br-E/VN Tag Stripping features, the hardware forwarding profile needs to be set. Setting the hardware forwarding profile will not affect the functionality of any other features that are supported while in Tap Aggregation mode. However, changing the forwarding profile does interrupt forwarding for a short period of time while the new configuration is applied.

### 21.1.9.1 Configuring Tap Aggregation Hardware Forwarding Profile

- The default hardware forwarding profile can be set globally with the **hardware forwarding system profile** command:

```
switch(config)# hardware forwarding system profile system-profile-tap-aggregation{/pre}

```

- When not in Tap Aggregation mode the default hardware forwarding profile should be returned to the default system profile with the same command:

```
switch(config)# hardware forwarding system profile system-profile-default{/pre}

```

- For a modular system the system default profile can also be overridden on a per line card basis with the command:

```
switch(config)# hardware forwarding module Linecard3 profile system-profile-tap-aggregation{/pre}

```

**Note:** If this command is used to set the hardware forwarding profile of a specific line card then changing the system default profile with the **hardware forwarding system profile** command will not affect that line card until the line card specific configuration is removed.

### 21.1.9.2 Show Commands

The following show command is available to see the hardware forwarding profile configuration:

```
(config) # show hardware forwarding profile
Linecard Configured Profile

FixedSystem system-profile-tap-aggregation
System default profile: system-profile-tap-aggregation
```

For a modular system, this example shows the system default profile, configured by **hardware forwarding system profile**, is set to **system-profile-default**. While the configuration for line cards **4** and **5** has been overridden and is set to **system-profile-tap-aggregation**.

```
(config) # show hardware forwarding profile
Linecard Configured Profile

Linecard3 system-profile-default
Linecard4 system-profile-tap-aggregation
Linecard5 system-profile-tap-aggregation
System default profile: system-profile-default
```

### 21.1.9.3 Limitations

Changing the hardware forwarding profile on the system or on a specific line card will interrupt forwarding on that system or line card for a short period of time.

## 21.1.10 TAP Aggregation MPLS Pop

The MPLS pop supports tools that do not parse MPLS labels and therefore need the switch to remove (pop) the MPLS header. The MPLS pop supports both IPv4 and IPv6 over MPLS.

### 21.1.10.1 Configuring MPLS Pop

- On DCS-7280R/R2, DCS-7500R/R2, and DCS-7020R MPLS pop is configurable at the tap port using the switchport command:

```
switch(config-if-Et1) # [no] switchport tap mpls pop all
```

- On DCS-7280R3, DCS-7500R3, and DCS7800R3 MPLS pop is configurable at the tool port using the switchport command. As the commands suggest, all MPLS labels will be popped.

```
switch(config-if-Et1) # [no] switchport tool mpls pop all
```

- On DCS-7280R3, DCS-7500R3, and DCS7800R3 the hardware forwarding profile must also be set before MPLS pop can be used. This is done globally by the command:

```
switch(config) # hardware forwarding system profile system-profile-tap-aggregation
```

- The system profile can also be overridden on a per line card basis with the command:

```
switch(config) # hardware forwarding module Linecard3 profile system-profile-tap-aggregation
```

### 21.1.10.2 Limitations

R/R2 series MPLS pop has the following limitations:

- New L2 Header on Egress
  - Always inserts a tap port Identity VLAN ID, even if not configured. Default Identity VID is 1.
  - Destination / source MAC addresses are not configurable.
- Tool Port / Egress VLAN Filtering
  - Because the incoming L2 header is discarded, the tool port does not have access to the original VLAN ID.
  - Tap ports can still filter on VLAN ID.
- ACL-Based Tap Aggregation
  - Matching IP headers contained inside an MPLS header is only supported since *EOS-4.20.5F*.

On both R/R2 series and R3 series some Tap Aggregation features do not work when forwarding MPLS-encapsulated traffic:

- Non-IP over MPLS
  - If the incoming L3 header is not recognized as IPv4 or IPv6 the MPLS pop feature is bypassed and the packet is not stripped.

### 21.1.11 TAP Aggregation 802.1br EVN Tag Stripping

802.1br-E/VN Tag Stripping feature for Tap Aggregation mode strips IEEE 802.1BR E-Tag and Cisco VN-Tag headers from all tagged packets received on tap interface before delivering them out of tool interfaces. Untagged packets are unaffected. The 802.1br EVN Tag Stripping may be useful for third-party tools and/or packet analyzers which cannot parse these headers.

#### 21.1.11.1 Configuring 802.1br-E/VN Tag Stripping

By default, Arista switches do not strip BR-E/VN tags from ingress packets.

On DCS-7280R/R2, DCS-7500R/R2, and DCS-7020R the BR-E/VN tag stripping is globally configured for Tap Aggregation. This means that packet ingressing any tap port will have their BR-E/VN tags stripped if the BR-E/VN tag stripping is enabled. The BR-E/VN tag stripping allows a choice of stripping both or either of the tags.

- To enable BR E-Tag stripping add the following configuration:

```
switch(config)# tap aggregation
switch(config-tap-agg)# [no] encapsulation dot1br strip
```

- To enable VN-TAG stripping add the following configuration:

```
switch(config)# tap aggregation
switch(config-tap-agg)# [no] encapsulation vn-tag strip
```

On DCS-7280R3, DCS-7500R3 and DCS7800R3, BR-E/VN tag stripping is configured at the tool port level. When enabled on a tool port, only packets egressing this tool port will have their BR-E/VN tags stripped. The BR-E/VN tag stripping allows a choice of stripping both or either of the tags.

- To activate BR E-Tag stripping on a tool port, add the following configuration:

```
switch(config-if-Et1)#[no] switchport tool encapsulation dot1br strip
```

- To activate VN-TAG stripping on a tool port, add the following configuration:

```
switch(config-if-Et1)#[no] switchport tool encapsulation vn-tag strip
```

On DCS-7280R3, DCS-7500R3, and DCS7800R3 the hardware forwarding profile must also be set before BR-E/VN tag stripping is used. This is done globally by the command:

```
switch(config)# hardware forwarding system profile system-profile-tap-aggregation
```

The system profile can also be overridden on a per line card basis with the command:

```
switch(config)# hardware forwarding module Linecard3 profile system-profile-tap-aggregation
```

### 21.1.11.2 Show Commands

The tap or tool ports with BR-E/VN tag stripping configured is verified with the following show commands.

- On DCS-7280R/R2, DCS-7500R/R2, and DCS-7020R:

```
switch(config)# show interfaces tap tunnel
 Port Configured Status Port Allowed Vlans Native Truncation
 Mode Identity
 ----- -----
 Et1/1 tap tap 0 All 1 0

 Port VN Tag Action BR Tag Action VXLAN Action MPLS Action
 ----- -----
 Et1/1 strip none none none
```

- On DCS-7280R3, DCS-7500R3, and DCS7800R3:

```
switch(config)# show interface tool tunnel
 Port Configured Status Id Tag Allowed Vlans Timestamp
 Mode Identity
 ----- -----
 Et1/1 tool tool Off 100 None

 Port VN Tag Action BR Tag Action MPLS Action
 ----- -----
 Et1/1 strip none none
```

### 21.1.11.3 Feature Interactions

On DCS-7280R/R2, DCS-7500R/R2, and DCS-7020R the following Tap aggregation features are supported with BR-E/VN tagged packets when tag stripping is enabled. Some or all of these features may not work for BR-E/VN tagged packets when tag stripping is not configured.

- MAC, IPv4, IPv6 Traffic Steering
- Tap identity tagging
- MPLS Termination
- Ingress VLAN Membership Filtering
- Egress VLAN Membership Filtering

On DCS-7280R3, DCS-7500R3, and DCS7800R3 the following Tap aggregation features are supported with BR-E/VN tagged packets when tag stripping is enabled.

- MAC, IPv4, IPv6 Traffic Steering
- Tap identity tagging

#### 21.1.11.4 Limitations

The following lists feature limitations on DCS-7280R/R2, DCS-7500R/R2, and DCS-7020R when BR-E/VN tag stripping is enabled with tagged packets:

- IPv4/IPv6 traffic steering on VLAN IDs is not supported.
- IPv6 traffic steering is not supported on packets with two or more accompanying 802.1Q tags.
- Ingress VLAN membership filtering is scale limited. Only **4096** entries, used for whitelisting or allowing specific port-VLAN pairs, are supported. The default case of allowing all VLANs does not consume any of these entries. For example, a tap interface configured to allow **4093** VLANs will consume all but three entries.
- Ingress VLAN membership filtering on Tap interface LAGs for BR-E/VN tagged packets is not supported. To use Ingress VLAN membership for BR-E/VN tagged packets on a LAG Tap interface the Ingress VLAN membership configuration must be configured on each physical interface of the LAG.
- Time stamping and BR-E/VN tag stripping cannot be configured on the same tool interfaces. Time stamping, if configured, will take precedence over BR-E/VN tag stripping.
- 802.1Q Tag Stripping does not support BR-E/VN tagged packets.

The following lists feature limitations on DCS-7280R3, DCS-7500R3, and DCS7800R3 when BR-E/VN tag stripping is enabled with tagged packets:

- IPv4/IPv6/MAC traffic steering on VLAN IDs is not supported.
- MPLS pop and BR-E/VN tag stripping can not be used simultaneously on a tool port. If MPLS pop and BR-E/VN tag stripping are both configured on the same tool port, MPLS pop will take precedence and BR-E/VN tags will not be stripped.
- Ingress and Egress VLAN Membership filtering of BR-E/VN tagged packets is not supported in *EOS-4.25.2F*.
- 802.1Q Tag Stripping does not support BR-E/VN tagged packets.

---

## 21.1.12 TAP Aggregation Commands

### Global Configuration Commands

- hardware forwarding system-profile-tap-aggregation
- platform fm6000 keyframe
- platform fm6000 keyframe device
- platform fm6000 keyframe fields skew
- platform fm6000 keyframe rate
- platform fm6000 keyframe source
- platform sand multicast replication default
- platform sand multicast replication ingress maximum
- tap aggregation

### Interface Configuration Commands

- mac runt
- mac timestamp
- switchport mpls pop all
- switchport tap allowed vlan
- switchport tap default group
- switchport tap identity
- switchport tap native vlan
- switchport tap truncation
- switchport tool allowed vlan
- switchport tool encapsulation
- switchport tool group
- switchport tool identity
- switchport tool truncation

### Tap Aggregation Configuration Mode

- encapsulation
- mode (tap-agg configuration mode)
- mode exclusive no-errdisable (tap-agg configuration mode)

### Tap Aggregation Traffic Steering

- class (policy-map (tapagg))
- class-map type tapagg
- match (class-map (tapagg))
- match (policy-map (tapagg))
- policy-map type tapagg
- resequence (class-map (tapagg))
- resequence (policy-map (tapagg))
- service-policy type tapagg (Interface mode)
- set (policy-map-class (tapagg))

**Display Commands EXEC Mode**

- [show hardware tcam profile](#)
- [show interfaces tap](#)
- [show interfaces tool](#)
- [show platform fm6000 keyframe](#)
- [show platform sand mcast capacity](#)
- [show tap aggregation groups](#)

---

### 21.1.12.1 class (policy-map (tapagg))

The `class (policy-map (tapagg))` command places the switch in the **policy-map-class** (TAPagg) configuration mode, which is a group-change mode that defines a TAP aggregation class by associating the class's eponymous class-map to a `set` statement. Upon exiting the policy-map-class mode, the class is placed in the policy-map as specified by an assigned sequence number.

A policy map is an ordered list of classes and match rules. Each class contains a class map, a `set` command, and a sequence number:

- The class map identifies a data stream by using an ordered list of ACLs. Class maps are configured in class-map (tapagg) configuration mode. Data packets are managed by commands of the highest priority class or rule that matches the packet.
- `set` commands specify the replication method of filtered data packets, either through an associated aggregation group or identity VLAN tagging.
- Sequence numbers specify the class's priority within the policy map. Lower sequence numbers denote higher priority.

The `exit` command returns the switch to policy-map configuration mode. However, saving policymap-class changes also requires an exit from policy-map mode. This saves all pending policy map and policy-map-class changes to **running-config** and returns the switch to global configuration mode. The `abort` command discards pending changes and returns the switch to global configuration mode.

The `no class` and `default class` commands remove the class assignment from the configuration mode policy map by deleting the corresponding class configuration from **running-config**.

#### Command Mode

Policy-Map (tapagg) Configuration accessed through `class (policy-map (tapagg))`

#### Command Syntax

```
[SEQ_NUM] class class_name
default [SEQ_NUM] class class_name
no [SEQ_NUM] class class_name
```

#### Parameters

- **SEQ\_NUM** priority of the class within the policy map. Lower numbers denote higher priority.
  - **no parameter** number is derived by adding 10 to number of the map's last class or rule.
  - **1 to 4294967295** number assigned to class.
- **class\_name** name of the class.

#### Guidelines

When a class is not associated with a `set (policy-map-class (tapagg))` command, the filtered traffic is managed as specified by the TAP port's default aggregation group.

#### Commands Available in Policy-map-class (tapagg) Configuration Mode

- `set (policy-map-class (tapagg))` assigns VLAN identity tag or tap aggregation group to class.
- `exit` returns the switch to parent policy map configuration mode.
- `abort` discards pending class map changes, then returns the switch to global configuration mode.

#### Related Commands

- `class (policy-map (tapagg))` places the switch in the **policy-map** (tapagg) configuration mode.

- **match (policy-map (tapagg))** assigns a match rule to a TAP aggregation policy map.

## Examples

- These commands place the switch in ***policy-map-class*** and add the ***t-class\_1*** class map to the ***t-policy\_1*** policy map. Packets filtered by the class map are identity tagged with **VLAN 444**.

```
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# class t-class_1
switch(config-pmap-c-t-policy_1-t-class_1)# set id-tag 444
switch(config-pmap-c-t-policy_1-t-class_1)# exit
switch(config-pmap-t-policy_1)# exit
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
10 class t-class_1
set id-tag 444
switch(config-pmap-t-policy_1)#

```

- These commands place the switch in **policy-map-class** to add the ***t-class\_1*** class map to the ***t-policy\_1*** policy map. The first, second, or both of the two outer-most VLAN tags are stripped.

```
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# class t-class_1
switch(config-pmap-t-policy_1-t-class_1)# set aggregation-group t-group remove dot1q outer 1-2
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group t-group id-tag 10
switch(config-pmap-c-t-policy_1-t-class_1)# set id-tag 10 remove dot1q outer 1
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group t-group
switch(config-pmap-c-t-policy_1-t-class_1)# set id-tag 10
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group t-group id-tag 10 remove
dot1q outer 1-2

```

### 21.1.12.2 class-map type tapagg

The **class-map type tapagg** command places the switch in class-map (tapagg) configuration mode, which is a group change mode that modifies a tapagg class map. A tapagg class map is a data structure that uses Access Control Lists (ACLs) to define a data stream by specifying characteristics of data packets that comprise the stream. Tapagg policy maps use class maps to specify traffic that is managed by policy map criteria.

The **exit** command saves pending class map changes to **running-config**, then returns the switch to the **global** configuration mode. Class map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes and returns the switch to global configuration mode.

The **no class-map type tapagg** and **default class-map type tapagg** commands delete the specified class map by removing the corresponding class-map type qos command and its associated configuration.

#### Command Mode

Global Configuration

#### Command Syntax

```
class-map type tapagg match-any class_name
no class-map type tapagg match-any class_name
default class-map type tapagg match-any class_name
```

#### Parameter

***class\_name*** name of class map.

#### Commands Available in Class-Map (tapagg) Configuration Mode

- [match \(class-map \(tapagg\)\)](#)
- [resequence \(class-map \(tapagg\)\)](#)

#### Related Commands

[class \(policy-map \(tapagg\)\)](#)

#### Example

This command creates a TAP aggregation class map named **t-class\_1** and places the switch in the **class-map** configuration mode.

```
switch(config)# class-map type tapagg match-any t-class_1
switch(config-cmap-t-class_1) #
```

### 21.1.12.3 encapsulation

The **encapsulation** command is configured under Tap Aggregation mode to enable the 802.1br-E/VN Tag Stripping the packets ingressing any tap port on DCS-7280R/R2, DCS-7500R/R2, and DCS-7020R.

The **no encapsulation** or **default encapsulation** commands disable the 802.1br-E/VN Tag Stripping configuration from the **running-config**.

#### Command Mode

Tap Aggregation Configuration Mode

## Command Syntax

```
encapsulation {dot1br | vn-tag} strip
no encapsulation {dot1br | vn-tag} strip
default encapsulation {dot1br | vn-tag} strip
```

## Parameters

- **dot1br** strips the 802.1br-E headers.
- **vn-tag** strips the VN Tag headers.

## Examples

- To enable BR E-Tag stripping add the following configuration:

```
switch(config)# tap aggregation
switch(config-tap-agg)# encapsulation dot1br strip
```

- To enable VN-TAG stripping add the following configuration:

```
switch(config)# tap aggregation
switch(config-tap-agg)# encapsulation vn-tag strip
```

### 21.1.12.4 hardware forwarding system-profile-tap-aggregation

The **hardware forwarding system-profile-tap-aggregation** command sets the global hardware forwarding system profile on a switch.

The **hardware forwarding system-profile-default** command returns the switch to the default system profile configurations when not in Tap Aggregation mode.

## Command Mode

Global Configuration Mode

## Command Syntax

```
hardware forwarding system profile [system-profile-default | system-profile-tap-aggregation | module]
```

```
default hardware forwarding system profile [system-profile-default | system-profile-tap-aggregation | module]
```

## Parameters

- **system-profile-default** normal forwarding profile.
- **system-profile-tap-aggregation** tap aggregation features profile.
- **module** used to set the tap aggregation features profile on a modular system.

## Examples

- This command configures the tap aggregation features profile.

```
switch(config)# hardware forwarding system profile system-profile-tap-aggregation
```

- This command returns the to the default system profile configurations when not in Tap Aggregation mode.

```
switch(config)# hardware forwarding system profile system-profile-default
```

- 
- This command overrides the system default profile on a per line card basis for a modular system.

```
switch(config)# hardware forwarding module Linecard3 profile system-profile-tap-aggregation
```

### 21.1.12.5 mac runt

The **mac runt** command configures runt packet behavior for TAP aggregation on the switch. A runt packet has a size smaller than the minimum allowed size, and typically caused by collisions on the network, hardware, or software issues. By default, the switch drops runt packets. The **no** version of the command removes the configuration from the ***running-config***.

#### Command Mode

TAP Aggregation configuration mode

#### Command Syntax

```
mac runt [drop | pad | pass-through]
```

#### Parameters

- **drop** - Drop packets below the runt threshold size.
- **pad** - Transmit runt packets after padding with an additional 64 bytes.
- **pass-through** - Allow runt packets to transmit without modification.

#### Example

To pad runt packets, use the following commands:

```
switch(config) # tap aggregation
switch(config-tap-agg) # mac runt pad
```

### 21.1.12.6 mac timestamp

The `mac timestamp` command enables timestamping on the configuration mode interface.

When timestamping is enabled on an egress interface, packets leave the interface with timestamps that were applied in hardware upon arriving at the switch. This is facilitated by applying a hardware timestamp to all frames arriving on all interfaces when timestamping is enabled on any interface, then removing timestamps on packets egressing interfaces where timestamping is not enabled.

The switch supports two timestamp modes, which differ in managing the egress frame's 32-bit Frame Check Sequence (FCS):

- **before-fcs**: the switch discards the original FCS, appends the ingress timestamp at the end of the frame data, recalculates a new FCS based on the appended timestamp, then appends the new FCS to the end of the frame. This creates a valid Ethernet frame but does not update headers of any nested protocols.
- **replace-fcs**: the switch replaces the original FCS with the timestamp. This mode maintains the size of the original frame without any latency impact, but the FCS is not valid.

The `no mac timestamp` and `default mac timestamp` commands restore the default behavior of disabling timestamping on the configuration mode interface by removing the corresponding `mac timestamp` command from *running-config*.

#### Command Mode

Interface-Ethernet Configuration

#### Command Syntax

`mac timestamp TS_PROPERTY`

#### Parameters

- **TS\_PROPERTY** specifies the timestamp insertion mode. Options include:
  - **before-fcs** the ingress timestamp is appended to the frame and the FCS is recalculated.
  - **replace-fcs** the ingress timestamp replaces the original FCS.

#### Examples

- These commands enable timestamping in **before-fcs** mode on **interface ethernet 44**.

```
switch(config)# interface ethernet 44
switch(config-if-Et44)# mac timestamp before-fcs
switch(config-if-Et44)# show active
interface Ethernet44
 mac timestamp before-fcs
switch(config-if-Et44) #
```

- These commands disable timestamping on **interface ethernet 44**.

```
switch(config-if-Et44)# no mac timestamp
switch(config-if-Et44)# show active
interface Ethernet44
switch(config-if-Et44) #
```

### 21.1.12.7 match (class-map (tapagg))

The **match** command adds an ACL to the configuration-mode class map and associates a sequence number to the ACL. A class map is an ordered list of ACLs that define a data stream; the sequence number specifies an ACL's priority within the list. A class map is used by policy maps to filter data packets. Tapagg class maps utilize ACL permit rules to pass packets and deny rules to drop packets.

Class map (tapagg) configuration mode is a group change mode. **Match** statements are not saved to **running-config** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the specified **match** statement from the configuration-mode class map by deleting the corresponding **match** command from **running-config**.

#### Command Mode

Class-map (tagagg) Configuration accessed through [class-map type tapagg](#) command.

#### Command Syntax

```
[SEQ_NUM] match ip access-group list_name
no SEQ_NUM] match ip access-group list_name
default SEQ_NUM] match ip access-group list_name
```

#### Parameters

- **SEQ\_NUM** sequence number assigned to the ACL. Options include:
  - **no parameter** number is derived by adding 10 to the number of the map's last ACL.
  - **1 to 4294967295** number assigned to ACL.
  - **list\_name** name of ACL assigned to class map.

#### Guidelines

**match** statements accept IPv4 ACLs.

#### Related Commands

- [class-map type tapagg](#) places the switch in Class-Map configuration mode.
- **exit** saves pending class map changes, then returns the switch to global configuration mode.
- **abort** discards pending class map changes, then returns the switch to global configuration mode.
- [class \(policy-map \(tapagg\)\)](#) assigns a class map to a policy map.

#### Example

These commands add two IPv4 ACLs (**tac1-1** and **tac1-2**) to the **t-class\_1** class map, save the command by exiting class-map mode, and re-enter the mode to display the added ACLs.

```
switch(config)# class-map type tapagg match-any t-class_1
switch(config-cmap-t-class_1)# match ip access-group tac1-1
switch(config-cmap-t-class_1)# match ip access-group tac1-2
switch(config-cmap-t-class_1)# exit
switch(config)# class-map type tapagg match-any t-class_1
switch(config-cmap-t-class_1)# show active
class-map type tapagg match-any t-class_1
 10 match ip access-group tac1-1
 20 match ip access-group tac1-2
switch(config-cmap-t-class_1)#

```

### 21.1.12.8 match (policy-map (tapagg))

The **match** command adds a rule to the configuration-mode TAP aggregation policy map. A policy map is an ordered list of classes and rules. Each rule contains a filter list, an action, and a sequence number:

- The filter list identifies a data stream through a set of packet field values.
- The action, (**SET\_VALUE** parameter) specifies the replication method of filtered data packets, either through an associated aggregation group or identity VLAN tagging.
- The sequence number specifies the rule's priority within the policy map.

The **no match** and **default match** commands remove the **match** rule from the configuration-mode policy by deleting the corresponding statement from *running-config*.

#### Command Mode

Policy-Map (tapagg) Configuration accessed through [class \(policy-map \(tapagg\)\)](#).

#### Command Syntax

```
[SEQ_NUM] match [VLAN_TAG] SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[PROTOCOL] [FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log]
SET_VALUE

no match [VLAN_TAG] SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [PROTOCOL]
[FLAGS][MESSAGE] [fragments][tracked] [DSCP_FILTER][TTL_FILTER] [log] SET_VALUE

default match [VLAN_TAG] SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[PROTOCOL][FLAGS] [MESSAGE][fragments] [tracked][DSCP_FILTER] [TTL_FILTER][log] SET_VALUE
```

**Note:** Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a permit rule.

#### Parameters

- **SEQ\_NUM** priority of the rule within the policy map. Lower numbers denote higher priority.
  - **no parameter** number derived by adding 10 to number of the map's last class or rule.
  - 1 to **4294967295** number assigned to class.
- **VLAN\_TAG** VLAN field filter. Options include:
  - **no parameter** packets are not filtered by VLAN field.
  - **vlan 1 to 4094 0 to 4095** VLAN ID and mask.
  - **vlan inner 1 to 4094 0 to 4095** VLAN ID and mask.
  - **vlan 1 to 4094 0 to 4095 inner 1 to 4094 0 to 4095** VLAN ID and mask.
- **PROTOCOL** protocol field filter. Values include:
  - **no parameter** packets are not filtered by host name.
  - **ahp** authentication header protocol (51).
  - **icmp** internet control message protocol (1).
  - **igmp** internet group management protocol (2).
  - **ip** internet protocol IPv4 (4).
  - **ospf** open shortest path first (89).
  - **pim** protocol independent multicast (103).
  - **tcp** transmission control protocol (6).
  - **udp** user datagram protocol (17).

- **vrrp** virtual router redundancy protocol (112).
- **protocol\_num** integer corresponding to an IP protocol. Values range from **0** to **255**.
- **SOURCE\_ADDR** and **DEST\_ADDR** source and destination address filters. Options include:
  - **network\_addr** subnet address (CIDR or address-mask).
  - **any** packets from all addresses are filtered.
  - **host ip\_addr** IP address (dotted decimal notation).

Source and destination subnet addresses support discontiguous masks.
- **SOURCE\_PORT** and **DEST\_PORT** source and destination port filters. Options include:
  - **any** all ports.
  - **eq port-1 port-2 ... port-n** a list of ports. Maximum list size is **10** ports.
  - **neq port-1 port-2 ... port-n** the set of all ports not listed. Maximum list size is **10** ports.
  - **gt port** the set of ports with larger numbers than the listed port.
  - **lt port** the set of ports with smaller numbers than the listed port.
  - **range port\_1 port\_2** the set of ports whose numbers are between the range.
- **fragments** filters packets with FO bit set (indicates a non-initial fragment packet).
- **FLAGS** flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
- **MESSAGE** message type filters (ICMP packets). Use CLI syntax assistance (?) to display options.
- **tracked** rule filters packets in existing ICMP, UDP, or TCP connections.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **DSCP\_FILTER** rule filters packet by its DSCP value. Values include:
  - **no parameter** rule does not use DSCP to filter packets.
  - **dscp dscp\_value** packets match if DSCP field in packet is equal to **dscp\_value**.
- **TTL\_FILTER** rule filters packet by its TTL (time-to-live) value. Values include:
  - **no parameter** rule does not use TTL field to filter packets.
  - **ttl eq ttl\_value** packets match if ttl in packet is equal to **ttl\_value**.
  - **ttl gt ttl\_value** packets match if ttl in packet is greater than **ttl\_value**.
  - **ttl lt ttl\_value** packets match if ttl in packet is less than **ttl\_value**.
  - **ttl neq ttl\_value** packets match if ttl in packet is not equal to **ttl\_value**.
- **log** triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **SET\_VALUE** specifies the replication method for filtered packets.
  - **set aggregation group agg\_group** replication specified by aggregation group.
  - **set id-tag 1 to 4094** packet is identity tagged with specified VLAN number.
  - **set aggregation group agg\_group id-tag 1 to 4094** assigns agg group and identity tag.

### Related Commands

- [policy-map type tapagg](#) places the switch in the **policy-map** (tapagg) configuration mode.
- [class \(policy-map \(tapagg\)\)](#) assigns a class to the configuration-mode policy map.

### Example

---

This command creates a match rule for the **t-policy\_1** policy map that filters OSPF packets and replicates them as specified by the **t-group** tap aggregation group.

```
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# match ip ospf any any set aggregation-group t-group
switch(config-pmap-t-policy_1)# exit
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
 10 match ip ospf any any set aggregation-group t-group
switch(config-pmap-t-policy_1)#

```

### 21.1.12.9 mode (tap-agg configuration mode)

The **mode** command configures the switch's TAP aggregation mode. The **mode exclusive** command enables TAP aggregation. When TAP aggregation is enabled, TAP and tool ports are enabled, switching mode is disabled, and switching ports are errdisabled. TAP aggregation is disabled by default.

The **no mode** and **default mode** commands disable TAP aggregation mode and enable switching mode by removing the **mode** command from *running-config*.

#### Command Mode

TAP Aggregation Configuration

#### Command Syntax

**mode exclusive**

**no mode exclusive**

**default mode exclusive**

#### Parameter

**exclusive** TAP aggregation is enabled.

#### Related Command

[tap aggregation](#) places the switch in the **TAP-aggregation** configuration mode.

#### Examples

- These commands place the switch in **tap aggregation** configuration mode, enable TAP aggregation mode, and display the results.

```
switch(config)# tap aggregation
switch(config-tap-agg)# mode exclusive
switch(config-tap-agg)# show active
 tap aggregation
 mode exclusive
switch(config-tap-agg) #
```

- These commands disable **tap aggregation** mode by removing the **mode** command from *running-config*, then display the results.

```
switch(config)# tap aggregation
switch(config-tap-agg)# no mode
switch(config-tap-agg)# show active
switch(config-tap-agg) #
```

---

### 21.1.12.10 mode exclusive no-errdisable (tap-agg configuration mode)

The **mode exclusive no-errdisable** command configures the specified interface to remain enabled, regardless of its switchport mode, when TAP aggregation is enabled. This command is used primarily to configure a port to support PTP functions while the switch operates as a TAP aggregator.

Each command configures one Ethernet or port-channel interface. Subsequent **mode exclusive no-errdisable** commands add to the list of ports that remain enabled when TAP aggregation is enabled.

The **no mode exclusive no-errdisable** and **default mode exclusive no-errdisable** commands configure the specified interface to be error-disabled when programmed in access, trunk, or dot1q-tunnel switching mode (when TAP aggregation is enabled) by removing the corresponding **mode exclusive no-errdisable** command from **running-config**.

#### Command Mode

TAP Aggregation Configuration

#### Command Syntax

**mode exclusive no-errdisable INT\_NAME**

#### Parameters

**INT\_NAME** interface type and number. Options include:

- **ethernet e\_num** Ethernet interface specified by **e\_num**.
- **port-channel p\_num** port-channel interface specified by **p\_num**.

#### Related Commands

- [tap aggregation](#) places the switch in **TAP-aggregation** configuration mode.
- [mode \(tap-agg configuration mode\)](#) configures the switch's TAP-aggregation mode.

#### Guidelines

In order for a TAP-aggregation switch to receive PTP traffic, the upstream device to which it is connected should be set to statically send PTP multicast traffic to the connected port on the switch.

Since IGMP snooping is disabled on TAP-aggregation switches and with no configuration to support sending upstream join messages in such a state, the messages are transmitted statically from the upstream device. Once the upstream messages are received, the port will move to the slave state and follow the standard PTP mechanism.

#### Example

These commands place the switch in TAP-aggregation configuration mode and place **interface ethernet 21/3** in no-errdisable mode.

```
switch(config)# tap aggregation
switch(config-tap-agg)# mode exclusive
switch(config-tap-agg)# mode exclusive no-errdisable ethernet 21/4
switch(config-tap-agg) #
```

### 21.1.12.11 platform fm6000 keyframe

The **platform fm6000 keyframe** command enables keyframe generation for data streams transmitted from specified ethernet interfaces. Keyframes are routable IP packets that the switch inserts into a data stream to provide contextual information that correlate timestamps inserted into data packets with absolute UTC time and the switch's complete ASIC time counter.

The switch supports a maximum of ten keyframes. The keyframe name is the label that distinguishes different keyframes. Each keyframe can egress from every ethernet port. Command options specify the destination MAC address and IP address in the keyframe's header. Other keyframe commands specify the transmission rate and the frame's source.

The **no platform fm6000 keyframe** and **default platform fm6000 keyframe** commands disable generation of the specified keyframe by deleting the corresponding platform fm6000 keyframe command from ***running-config***. These command also remove all supporting **platform fm6000 keyframe** commands for the specified keyframe.

#### Command Mode

Global Configuration

#### Command Syntax

```
platform fm6000 keyframe kf_name interface ethernet [e_range ipv4_addr mac_addr
no platform fm6000 keyframe kf_name
default platform fm6000 keyframe kf_name
```

#### Parameters

- ***kf\_name*** the keyframe's name.
- ***e\_range*** Ethernet interface range over which the keyframe egresses. Valid formats include number, range, or comma-delimited list of numbers and ranges.
- ***ipv4\_addr*** destination IPv4 address inserted into keyframes (dotted decimal notation).
- ***mac\_addr*** destination MAC address inserted into keyframes (48-bit dotted hex notation).

#### Guidelines

Subsequent issuance of this command for a specified keyframe replaces the existing command in ***running-config***. Ethernet interfaces are inserted into an existing keyframe only by issuing the complete command that identifies all interfaces through which the keyframe is transmitted.

#### Example

This command enables the generation of a keyframe named **key-1**. This keyframe egresses from Ethernet interfaces **11** through **15** and specifies a source IP address of **10.21.1.4** and a MAC address of **10.4E21.9F11**.

```
switch(config)# platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
switch(config) #
```

---

### 21.1.12.12 platform fm6000 keyframe device

The **platform fm6000 keyframe device** command configures the 16-bit number that the specified keyframe lists as the device ID in its payload. By default, the device value placed in the specified keyframes is **0**.

The **no platform fm6000 keyframe device** and **default platform fm6000 keyframe device** commands restore the default device ID insertion value of **0** for the specified keyframe by removing the corresponding **platform fm6000 keyframe device** command from **running-config**. The **no platform fm6000 keyframe** and **default platform fm6000 keyframe** command also removes the corresponding **platform fm6000 keyframe device** command from **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
platform fm6000 keyframe kf_name device device_id
no platform fm6000 keyframe kf_name device
default platform fm6000 keyframe kf_name device
```

#### Parameters

- ***kf\_name*** keyframe name.
- ***device\_id*** value inserted in keyframe's device ID field. Values range from **0** to **65535**. Default is **0**.

#### Example

These commands enable the generation of a keyframe named **key-1**, then configure **100** as the value that is placed in the keyframe's device ID field.

```
switch(config)# platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
switch(config)# platform fm6000 keyframe key-1 device 100
switch(config)#{
```

### 21.1.12.13 platform fm6000 keyframe fields skew

Keyframes may optionally include skew numerator and skew denominator fields. These skew fields form a ratio indicating the ASIC clock skew. If the ratio is greater than **1**, the clock is skewed fast; if the ratio is less than **1**, the clock is skewed slow. Clock skew fields are omitted by default.

The **platform fm6000 keyframe fields skew** command enables the inclusion of clock skew fields in the keyframe.

The **no platform fm6000 keyframe fields skew** and **default platform fm6000 keyframe fields skew** commands remove the clock skew fields from the keyframe.

#### Command Mode

Global Configuration

#### Command Syntax

```
platform fm6000 keyframe kf_name fields skew
```

#### Parameter

*kf\_name* keyframe name.

#### Example

This command enables the inclusion of clock skew fields in the keyframe named **key-1**.

```
switch(config)# platform fm6000 keyframe key-1 fields skew
switch(config)#
```

---

#### 21.1.12.14 platform fm6000 keyframe rate

The **platform fm6000 keyframe rate** command specifies the transmission rate for the specified keyframe from each interface from which it is configured to egress. By default, one keyframe is sent per second.

The **no platform fm6000 keyframe rate** and **default platform fm6000 keyframe rate** commands restore the default transmission rate for the specified keyframe of one per second by removing the corresponding **platform fm6000 keyframe rate** command from **running-config**. The **no platform fm6000 keyframe** and **default platform fm6000 keyframe** command also removes the corresponding **platform fm6000 keyframe rate** command from **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
platform fm6000 keyframe kf_name rate tx_rate
```

#### Parameters

- ***kf\_name*** the keyframe's name.
- ***tx\_rate*** keyframe transmission rate (frames per second). Values range from **1** to **100**. Default value is **1**.

#### Example

These commands enable the generation of a keyframe named **key-1**, then configure the generation rate for the keyframe of **10** frames per second on each of the five interfaces that it is configured to egress.

```
switch(config)# platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
switch(config)# platform fm6000 keyframe key-1 rate 10
switch(config) #
```

### 21.1.12.15 platform fm6000 keyframe source

The **platform fm6000 keyframe source** command configures the source IP address that the specified keyframe lists in its IP header. By default, keyframes use the IP address of the management interface as their source address.

The **no platform fm6000 keyframe source** and **default platform fm6000 keyframe source** commands restore the management interface IP address as the specified keyframe's source IP address by removing the corresponding **platform fm6000 keyframe source** command from **running-config**. The **no platform fm6000 keyframe** and **default platform fm6000 keyframe** command also removes the corresponding **platform fm6000 keyframe source** command from **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
platform fm6000 keyframe kf_name source ip ipv4_addr
no platform fm6000 keyframekf_name source ip
default platform fm6000 keyframe kf_name source ip
```

#### Parameters

- ***kf\_name*** keyframe's name.
- ***ipv4\_addr*** keyframe's source IPv4 address (dotted decimal notation).

#### Example

These commands enable the generation of a keyframe named **key-1**, then sets the keyframe source IP address to **10.1.1.101**.

```
switch(config)# platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
switch(config)# platform fm6000 keyframe key-1 source 10.1.1.101
switch(config)#{
```

---

### 21.1.12.16 platform sand multicast replication default

The **platform sand multicast replication default** command configures the default replication mode on Sand platform switches. The factory default replication mode differs in various scenarios as follows:

- The default replication mode on switches with fabric is **fabric-egress** mode.
- The default replication mode on switches with single Fabric Access Processor (FAP) systems is **ingress** mode.
- The default replication mode on switches without fabric barring single FAP systems is **ingress-egress** mode.
- If a tool group with less than **60** LAGs has at least one hardware LAG, then the default replication mode of the tool group is **ingress-only** mode. Else the default replication mode of the tool group is the one configured across all LAGs in the tool group.

The **default platform sand multicast replication default** and **no platform sand multicast replication default** commands revert the current state to the factory default behavior.

#### Command Mode

Global Configuration

#### Command Syntax

```
platform sand multicast replication default {fabric-egress | ingress}
no platform sand multicast replication default
default platform sand multicast replication default
```

#### Parameters

- **fabric-egress** configures the replication mode to use fabric-egress VoQ buffers.
- **ingress** configures the replication mode to use ingress VoQ buffers.

#### Guidelines

This command is supported on Sand platforms only.

#### Related Commands

- [platform sand multicast replication ingress maximum](#)
- [show platform sand mcast capacity](#)

#### Example

This command configures the default replication mode to ingress.

```
switch(config)# platform sand multicast replication default ingress
switch(config)#[/pre]
```

## 21.1.12.17 platform sand multicast replication ingress maximum

The `platform sand multicast replication ingress maximum` command configures maximum members for ingress-only replication.

The `default platform sand multicast replication ingress maximum` command reverts the maximum members for ingress-only replication to the default value.

The `no platform sand multicast replication ingress maximum` command deletes the maximum member value for ingress-only replication.

### Command Mode

Global Configuration

### Command Syntax

```
platform sand multicast replication ingress maximum max_value
```

```
no platform sand multicast replication ingress maximum
```

```
default platform sand multicast replication ingress maximum
```

### Parameters

***max\_value*** specifies the maximum number of members for ingress-only replication. Values range from **1** to **64**. The default value is **64**.

**Note:** *max\_value* for a single FAP Jericho system ranges from **1** to **4096**.

### Guidelines

This command is supported on Sand platforms only.

### Related Commands

- [platform sand multicast replication default](#)
- [show platform sand mcast capacity](#)

### Example

This command specifies a maximum of **63** members for ingress-only replication.

```
switch(config)# platform sand multicast replication ingress maximum 63
switch(config)#

```

---

## 21.1.12.18 policy-map type tapagg

The **policy-map type tapagg** command places the switch in policy-map (tapagg) configuration mode, which is a group-change mode that modifies a TAP-aggregation policy map. A TAP-aggregation policy map is a data structure that consists of class maps and match statements that filter a specific data stream. Packets in that data stream are either managed as specified by a TAP aggregation group or modified to add a VLAN identity tag. Policy maps manage traffic when applied to an Ethernet or port-channel interface.

The **exit** command saves pending policy map changes to ***running-config*** and returns the switch to global configuration mode. Policy map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes, returning the switch to global configuration mode.

The **no policy-map type tapagg** and **default policy-map type tapagg** commands delete the specified policy map by removing the corresponding **policy-map type tapagg** command and the associated policy map statements from ***running-config***.

### Command Mode

Global Configuration

### Command Syntax

```
policy-map type tapagg map_name
no policy-map type tapagg map_name
default policy-map type tapagg map_name
```

### Parameter

***map\_name*** name of policy map.

### Commands Available in Policy-Map Configuration Mode

- [class \(policy-map \(tapagg\)\)](#)
- [match \(policy-map \(tapagg\)\)](#)

### Related Commands

- [class-map type tapagg](#)
- [service-policy type tapagg \(Interface mode\)](#)

### Example

This command creates the TAP-aggregation policy map named ***t-policy\_1*** and places the switch in the **policy-map** configuration mode.

```
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1) #
```

### 21.1.12.19 resequence (class-map (tapagg))

The **resequence** command assigns sequence numbers to access control lists (ACLs) in the configuration mode TAP-aggregation class map. Sequence numbers denote an ACL's priority within the class map. Command parameters specify the number of the first ACL and the numeric interval between consecutive ACLs.

Maximum rule sequence number is **4294967295**.

#### Command Mode

Class-map (tagagg) Configuration

accessed with the [class-map type tapagg](#) command

#### Command Syntax

```
resequence [start_num [inc_num]]
```

#### Parameters

- ***start\_num*** sequence number assigned to the first rule. Default is **1**.
- ***inc\_num*** numeric interval between consecutive rules. Default is **1**.

#### Example

These commands display a policy map whose entities were entered with default sequence numbers, then renumber the contents.

```
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
 10 match ip ospf any any set aggregation-group t-group
 20 class fred
 set aggregation-group t-group id-tag 444
 30 class t-class_2
 set id-tag 500
 40 class t-class_3
 set id-tag 600
 50 class t-class_4
 set id-tag 700
switch(config-pmap-t-policy_1)# resequence 100 20
switch(config-pmap-t-policy_1)# exit
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
 100 match ip ospf any any set aggregation-group t-group
 120 class fred
 set aggregation-group t-group id-tag 444
 140 class t-class_2
 set id-tag 500
 160 class t-class_3
 set id-tag 600
 180 class t-class_4
 set id-tag 700
switch(config-pmap-t-policy_1)#

```

---

## 21.1.12.20 resequence (policy-map (tapagg))

The **resequence** command assigns sequence numbers to classes and rules in the configuration mode TAP-aggregation policy map. Sequence numbers denote the priority of a class or rule within the policy map. Command parameters specify the number of the first policy map entity and the numeric interval between consecutive entities.

Maximum rule sequence number is **4294967295**.

### Command Mode

Policy-Map (tapagg) Configuration accessed with the [class \(policy-map \(tapagg\)\)](#) command

### Command Syntax

```
resequence [start_num [inc_num]]
```

### Parameters

- **start\_num** sequence number assigned to the first rule. Default is **1**.
- **inc\_num** numeric interval between consecutive rules. Default is **1**.

### Example

These commands display a policy map whose entities were entered with default sequence numbers, then use the **resequence** command to renumber the contents.

```
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
 10 match ip ospf any any set aggregation-group t-group
 20 class fred
 set aggregation-group t-group id-tag 444
 30 class t-class_2
 set id-tag 500
 40 class t-class_3
 set id-tag 600
 50 class t-class_4
 set id-tag 700
switch(config-pmap-t-policy_1)# resequence 100 20
switch(config-pmap-t-policy_1)# exit
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
 100 match ip ospf any any set aggregation-group t-group
 120 class fred
 set aggregation-group t-group id-tag 444
 140 class t-class_2
 set id-tag 500
 160 class t-class_3
 set id-tag 600
 180 class t-class_4
 set id-tag 700
switch(config-pmap-t-policy_1)#

```

### 21.1.12.21 service-policy type tapagg (Interface mode)

The **service-policy type tapagg** command applies a specified TAP-aggregation policy map to the configuration-mode interface. A policy map is a data structure that identifies data traffic through class maps and match rules, then specifies the method of replicating the traffic. This command is active only when TAP aggregation mode is enabled on the switch.

The **no service-policy type tapagg** and **default service-policy type tapagg** commands remove the policy map assignment from the configuration mode interface by deleting the corresponding **service-policy tapagg** command from ***running-config***.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

#### Command Syntax

**service-policy type tapagg input *map\_name***

#### Parameters

- **input** policy map applies to inbound packet streams. This is the only option.
- ***map\_name*** name of policy map.

#### Guidelines

A policy map that is attached to a port-channel interface takes precedence for member interfaces of the port channel over their individual Ethernet interface configuration. Members that are removed from a port channel revert to the policy-map implementation specified by its Ethernet interface configuration.

#### Related Commands

[class \(policy-map \(tapagg\)\)](#) places the switch into the **policy-map** configuration mode to create a policy map.

#### Example

These commands apply the **t-policy\_1** policy map to **interface ethernet 17**.

```
switch(config)# interface ethernet 17
switch(config-if-Et17)# service-policy type tapagg input t-policy_1
switch(config-if-Et17)#

```

### 21.1.12.22 set (policy-map-class (tapagg))

The **set** command specifies the data replication method for traffic filtered by the associated class map in the configuration-mode policy map. The **set** command specifies one of these replication actions for filtered data packets:

- specifies an aggregation group.
- specifies a VLAN identity tag for replicated packets.
- specifies an aggregation group and a VLAN identity tag.

The **no set** and **default set** commands remove the specified set command data action from the configuration-mode class by deleting the associated **set** command from **running-config**.

#### Command Mode

Policy-map-class (tapagg) Configuration accessed using the [class \(policy-map \(tapagg\)\)](#) command

#### Command Syntax

```
set SET_VALUE
no set SET_VALUE
default set SET_VALUE
```

#### Parameters

**SET\_VALUE** specifies the replication method for filtered packets. Options include:

- **aggregation group agg\_group** replication specified by aggregation group.
- **id-tag VLAN\_number** packet is identity tagged with specified VLAN number. VLAN numbers range from **1** to **4094**.
- **aggregation group agg\_group id-tag VLAN\_number** assigns aggregation group and identity tag (VLAN number). VLAN numbers range from **1** to **4094**.

#### Related Commands

- [policy-map type tapagg](#) places the switch in the **policy-map** (tapagg) configuration mode.
- [class \(policy-map \(tapagg\)\)](#) assigns a class to the **policy-map** configuration mode.
- [match \(policy-map \(tapagg\)\)](#) assigns a rule to the **policy-map** configuration mode.

#### Guidelines

When a class is not associated with a **set** command, the filtered traffic is managed as specified by the TAP port's default aggregation group.

#### Example

These commands place the switch in policy-map-class to add the **t-class\_1** class map to the **t-policy\_1** policy map. Packets filtered by the class map are identity tagged with **vlan 444** and replicated as specified through the **t-group** aggregation group.

```
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# class t-class_1
switch(config-pmap-c-t-policy_1-t-class_1)# set aggregation-group t-group id-tag 444
switch(config-pmap-c-t-policy_1-t-class_1)# exit
switch(config-pmap-t-policy_1)# exit
switch(config)# policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)# show active
policy-map type tapagg t-policy_1
 10 class t-class_1
```

```
 set aggregation-group t-group id-tag 444
switch(config-pmap-t-policy_1) #
```

---

### 21.1.12.23 show hardware tcam profile

Use the **show hardware tcam profile** command to display The TCAM prifile by configuration and status.

#### Command Mode

EXEC

#### Command Syntax

```
show hardware tcam profile detail
```

#### Parameter

**detail** Displays TCAM profile details.

#### Example

```
(config-tap-agg) # show hardware tcam profile
 Configuration Status
FixedSystem foo* foo
* configuration overridden by TapAgg
```

### 21.1.12.24 show interfaces tap

The **show interfaces tap** command displays TAP-port configuration information for the specified interfaces.

#### Command Mode

EXEC

#### Command Syntax

```
show interfaces [INTERFACE] tap [INFO_LEVEL]
```

#### Parameters

- **INTERFACE** interface type and numbers. Options include:
  - **no parameter** all interfaces.
  - **ethernet e\_range** Ethernet interface range specified by **e\_range**.
  - **management m\_range** management interface range specified by **m\_range**.
  - **port-channel p\_range** port-channel interface range specified by **p\_range**.
  - Valid **e\_range**, **m\_range**, and **p\_range** formats include number, number range, or comma-delimited list of numbers and ranges.
- **INFO\_LEVEL** amount of information that is displayed. Options include:
  - **no parameter** command displays table that summarizes TAP data.
  - **detail** command displays TAP data summary table and a list of ACLS applied to TAP ports.

#### Examples

- This command displays TAP-port configuration information for interface ethernet **36** through **40**.

```
switch# show interface ethernet 31-35 tap
Port Configured Status Native Id Truncation Default
Mode Mode Mode Vlan Vlan

Et31 tap tap 301 31 0 tag_1
Et32 tap tap 1 132 0 tag_1
Et33 tap tap 303 233 0 tag_1
Et34 tap tap 1 334 0 tag_3
Et35 tap tap 1 345 0 tag_3
switch#
```

- This command displays detailed TAP-port configuration information for **interface ethernet 17**.

```
switch# show interface ethernet 17 tap detail
Port Configured Status Native Id Truncation Default
Mode Mode Mode Vlan Vlan

Et31 tap tap 301 31 0 tag_1

Port ACLs Applied

switch#
```

---

### 21.1.12.25 show interfaces tool

The **show interfaces tool** command displays tool port configuration information for the specified interfaces.

#### Command Mode

EXEC

#### Command Syntax

```
show interfaces [INTERFACE] tool
```

#### Parameters

**INTERFACE** interface type and numbers. Options include:

- **no parameter** all interfaces.
- **ethernet e\_range** Ethernet interface range specified by **e\_range**.
- **management m\_range** management interface range specified by **m\_range**.
- **port-channel p\_range** port-channel interface range specified by **p\_range**.

Valid **e\_range**, **m\_range**, and **p\_range** formats include number, number range, or comma-delimited list of numbers and ranges.

#### Example

This command displays tool port configuration information for interface ethernet **36** through **40**.

| Port  | Configured Mode | Status      | Allowed Vlans | Id Tag | Timestamp Mode |
|-------|-----------------|-------------|---------------|--------|----------------|
| <hr/> |                 |             |               |        |                |
| Et36  | tool            | tool        | 201-205       | Off    | None           |
| Et37  | tool            | tool        | 201-205       | Off    | None           |
| Et38  | tool            | tool        | 201-205       | Off    | None           |
| Et39  | access          | errdisabled | All           | Off    | None           |
| Et40  | tool            | tool        | All           | On     | None switch#   |

### 21.1.12.26 show platform fm6000 keyframe

The **show platform fm6000 keyframe** command displays configured information for the specified keyframes. Keyframes are routable IP packets that the switch inserts into a data stream to provide contextual information that correlate timestamps inserted into data packets with the absolute UTC time and the switch's complete ASIC time counter.

#### Command Mode

Privileged EXEC

#### Command Syntax

```
show platform fm6000 keyframe [KEYFRAME_ID]
```

#### Parameters

**KEYFRAME\_ID** specifies keyframes that the command displays. Options include:

- **no parameter** command displays all configured keyframes.
- **kf\_name** specifies a single keyframe to display information for.

#### Example

This command displays information concerning the three keyframes that the switch sends.

```
switch# show platform fm6000 keyframe
Keyframe key-2

Egress Interface(s): Ethernet17, Ethernet18, Ethernet19, Ethernet20, Ethernet21
Source IP: 10.22.30.144
Destination IP: 10.21.1.14
Destination MAC: 00:09:00:09:00:09
Device ID: 0
Rate: 5 packet(s) per second

Keyframe key-1

Egress Interface(s): Ethernet11, Ethernet12, Ethernet13, Ethernet14, Ethernet15
Source IP: 10.22.30.146
Destination IP: 10.21.1.4
Destination MAC: 00:10:4e:21:9f:11
Device ID: 0
Rate: 2 packet(s) per second switch#
```

---

## 21.1.12.27 show platform sand mcast capacity

The **show platform sand mcast capacity** command displays the usage details of hardware resources on Sand platform switches.

### Command Mode

EXEC

### Command Syntax

```
show platform sand mcast capacity [threshold threshold_value]
```

### Parameter

**threshold *threshold\_value*** displays the list of resources whose usage percentage is greater than or equal to the specified threshold value. Values range from **0** to **100**. The default value is **100**.

### Guidelines

This command is supported on Sand platforms only.

### Example

This command displays the usage details of hardware resources on a Sand platform switch.

```
switch# show platform sand mcast capacity

Multicast Resources

'*' - Applies to all Modules
'-' - Not applicable
 TCAM Resources

Resource Module Total Used Used%
v4 MC TCAM Linecard3-Jericho3/0 4096 2 0.0
v4 MC TCAM Linecard5-Jericho5/0 4096 506 12.4

 Replication Table Resources

Resource Module Total Used Used%
Multicast Table Row
Linecard3-Jericho3/0.0 262143 10586 4.0
Linecard3-Jericho3/1.0 262143 10576 4.0
Linecard3-Jericho3/0.1 262143 10586 4.0
Linecard3-Jericho3/1.1 262143 10576 4.0
Linecard6-Jericho6/2.0 262143 10576 4.0
switch#
```

### 21.1.12.28 show tap aggregation groups

The **show tap aggregation groups** command displays the TAP and tool port members of the specified TAP aggregation groups.

#### Command Mode

EXEC

#### Command Syntax

```
show tap aggregation groups [INFO_LEVEL] [GROUP_NAMES]
```

#### Parameters

- **INFO\_LEVEL** port information to display. Options include:
  - **no parameter** displays active TAP and tool ports.
  - **detail** displays all configured TAP and tool ports, including inactive ports.
- **GROUP\_NAMES** TAP aggregation groups. Options include:
  - **no parameter** displays information for all TAP aggregation groups.
  - **group\_list** displays information for the specified TAP aggregation group list.

Valid **group\_list** format is a space-delimited list of one or more TAP aggregation group names.

#### Example

This command displays the contents of all configured TAP aggregation groups.

```
switch# show tap aggregation groups
Group Name Tool Members

analyze2 Po101, Po102
analyze3 Po101, Po103

Group Name Tap Members

analyze2 Et41, Et42
analyze3 Et43 switch#
```

### 21.1.12.29 switchport mpls pop all

The **switchport mpls pop all** command configures the MPLS Pop on the switch.

- On DCS-7280R/R2, DCS-7500R/R2, and DCS-7020R MPLS pop is configurable at the tap port using the **switchport** command.
- On DCS-7280R3, DCS-7500R3, and DCS7800R3 MPLS pop is configurable at the tool port using the **switchport** command.
- On DCS-7280R3, DCS-7500R3, and DCS7800R3 the hardware forwarding profile must also be set before MPLS pop can be used.

The **no switchport mpls pop all** command removes the switchport configuration by modifying the corresponding statements in **running-config**.

#### Command Mode

Interface-Ethernet Configuration

#### Command Syntax

---

```
switchport [tool | tap] mpls pop all
no switchport [tool | tap] mpls pop all
```

#### Parameters

- **tool** Tool port configuration.
- **tap** Tap port configuration.

#### Example

This command configures the MPLS Pop at the Tap port on the switch.

```
switch(config-if-Et1)# [no] switchport tap mpls pop all
```

### 21.1.12.30 switchport tap allowed vlan

The **switchport tap allowed vlan** command creates or modifies the list of VLANs for which the configuration mode interface, in TAP mode, handles tagged traffic. By default, interfaces handle tagged traffic for all VLANs. Command settings persist in ***running-config*** without taking effect when the switch is not in TAP aggregation mode or the interface is not in TAP aggregation mode.

The **no switchport tap allowed vlan** and **default switchport tap allowed vlan** commands restore the TAP mode default allowed VLAN setting of **all** by removing the corresponding **switchport tap allowed vlan** statement from ***running-config***.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

`switchport tap allowed vlan EDIT_ACTION`

#### Parameters

**EDIT\_ACTION** modifications to the VLAN list. Options include:

- **v\_range** creates VLAN list from range of VLANs specified by **v\_range**.
- **add v\_range** adds specified VLANs to current list.
- **all** VLAN list contains all VLANs.
- **except v\_range** VLAN list contains all VLANs except those specified by **v\_range**.
- **none** VLAN list is empty (no VLANs).
- **remove v\_range** removes VLANs specified by **v\_range** from current list.

#### Example

These commands create the TAP mode allowed VLAN list of **26-30** for **interface ethernet 20**.

```
switch(config)# interface ethernet 20
switch(config-if-Et20)# switchport tap allowed vlan 26-30
eswitch(config-if-Et20)# show active
interface Ethernet20
 switchport mode tap
 switchport tap allowed vlan 26-30
switch(config-if-Et20)#

```

---

### 21.1.12.31 switchport tool encapsulation

The **switchport tool encapsulation** command is configured under Ethernet Interface configuration mode. When enabled on a tool port, only packets egressing this tool port will have their BR-E/VN tags stripped on DCS-7280R3, DCS-7500R3 and DCS7800R3.

The **no switchport tool encapsulation** or **default switchport tool encapsulation** commands disables the 802.1br-E/VN Tag Stripping from the **running-config**.

#### Command Mode

Interface-Ethernet Configuration Mode

#### Command Syntax

```
switchport tool encapsulation {dot1br | vn-tag} strip
no switchport tool encapsulation dot1br | vn-tag} strip
defualt switchport tool encapsulation dot1br | vn-tag} strip
```

#### Parameters

- **dot1br** strips the 802.1br-E headers.
- **vn-tag** strips the VN Tag headers.

#### Examples

- To activate BR E-Tag stripping on a tool port, add the following configuration:

```
switch(config-if-Et1)# [no] switchport tool encapsulation dot1br strip
```

- To activate VN-TAG stripping on a tool port, add the following configuration:

```
switch(config-if-Et1)# [no] switchport tool encapsulation vn-tag strip
```

### 21.1.12.32 switchport tap default group

The **switchport tap default group** command assigns the configuration-mode interface to the specified tool group as a TAP port member. TAP aggregation groups associate a set of TAP ports with a set of tool ports. Both TAP ports and tool ports may belong to multiple TAP aggregation groups.

The **no switchport tap default group** and **default switchport tap default group** commands remove the configuration-mode interface from the TAP aggregation group to which it is assigned by deleting the corresponding **switchport tap default group** statement from *running-config*.

#### Command Mode

Interface-Ethernet Configuration

Interface-port Channel Configuration

#### Command Syntax

```
switchport tap default group group_name
no switchport tap default group
default switchport tap default group
```

#### Parameter

**group\_name** tool group name.

#### Restriction

This command is available on FM6000 platform switches only.

#### Example

These commands assign **port channel 101** to TAPs aggregation group **tag-1**.

```
switch(config)# interface port-channel 101
switch(config-if-Po101)# switchport tap default group tag-1
switch(config-if-Po101)# show interfaces port-channel 101 tap
Port Configured Status Native Id Truncation Default
Mode Mode Vlan Vlan

Po101 access notconnect 1 1 0 tag-1
switch(config)#

```

---

### 21.1.12.33 switchport tap identity

The **switchport tap identity** command associates a VLAN number to the configuration mode TAP interface. Tool ports that are configured to encapsulate packets with an dot1q-style tag enter the number specified by this command as the s-VLAN (tier 1) for packets received from this TAPs port. The default identity value is 1.

The **no switchport tap identity** and **default switchport tap identity** commands restore **vlan 1** as the configuration-mode ports's identity VLAN by removing the corresponding **switchport tap identity** command from *running-config*.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

```
switchport tap identity port_id
no switchport tap identity
default switchport tap identity
```

#### Parameter

***port\_id*** port's identity VLAN. Values range from **1** to **4094**. Default is **1**.

#### Related Commands

[switchport tool identity](#) configures a tool port to encapsulate packets received from TAP ports.

#### Restriction

This command is available only on FM6000 platform switches.

#### Example

These commands **171** as the identity value for **interface ethernet 17**.

```
switch(config)# interface ethernet 17
switch(config-if-Et17)# switchport tap identity 171
switch(config-if-Et17)# show active
interface Ethernet17
 switchport tap identity 171
switch(config-if-Et17)# show interfaces ethernet 17 tap

Port Configured Status Native Id Truncation Default
Mode Mode Status Vlan Vlan Group

Et17 access connected 1 171 0
switch(config-if-Et17)#

```

### 21.1.12.34 switchport tap native vlan

The **switchport tap native vlan** command specifies the TAP-mode native VLAN for the configuration-mode interface. Interfaces in TAP mode associate untagged frames with the native VLAN. The default native VLAN for all interfaces is **vlan 1**. Command settings persist in **running-config** without taking effect when the switch is not in TAP aggregation mode or the interface is not in TAP mode.

The **no switchport tap native vlan** and **default switchport tap native vlan** commands restore **vlan 1** as the TAP-mode native VLAN to the configuration-mode interface by removing the corresponding **switchport tap native vlan** command from **running-config**.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

```
switchport tap native vlan v_num
no switchport tap native vlan
default switchport tap native vlan
```

#### Parameter

**v\_num** TAP-mode native VLAN ID. Values range from 1 to 4094. Default is 1.

#### Restriction

This command is available only on FM6000 platform switches.

#### Example

These commands assign **vlan 25** as the TAP-mode native VLAN for **interface ethernet 7**.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# switchport tap native vlan 25
switch(config-if-Et7)# show interface ethernet 7 tap
Port Configured Status Native Id Truncation Default
Mode Mode Vlan Vlan Group

switch(config-if-Et7) #
```

---

### 21.1.12.35 switchport tap truncation

The **switchport tap truncation** command configures the configuration-mode interface, as a TAP port, to truncate inbound packets to the specified packet size. This command is in effect when the port is in TAP mode and the switch is in TAP aggregation mode. Command settings persist in **running-config** without taking effect when the switch is not in TAP aggregation mode or the interface is not in TAP mode. By default, TAP ports do not truncate inbound packets.

The **no switchport tap truncation** and **default switchport tap truncation** commands restore the default behavior of not truncating packets received by the configuration-mode interface by removing the corresponding **switchport tap truncation** command from **running-config**.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

```
switchport tap truncation packet_size
no switchport tap truncation
default switchport tap truncation
```

#### Parameter

**packet\_size** size of truncated packets (bytes). Values range from **100** to **9236**. Default value of **0** corresponds to not truncating packets.

#### Restriction

This command is available only on FM6000 platform switches.

#### Examples

- These commands configure **interface ethernet 38** to truncate packets to **150** bytes.

```
switch(config)# interface ethernet 38
switch(config-if-Et38)# switchport tap truncation 150
switch(config-if-Et38)# show interface ethernet 38 tap
Port Configured Status Native Id Truncation Default
Mode Mode Mode Vlan Vlan
-----+-----+-----+-----+-----+-----+-----+-----+
Et38 access notconnect 1 1 150 ---
```

- These commands configure **interface ethernet 38** to send complete packets to tool ports in its TAP aggregation group.

```
switch(config-if-Et38)# no switchport tap truncation
switch(config-if-Et38)# show interface ethernet 38 tap
Port Configured Status Native Id Truncation Default
Mode Mode Mode Vlan Vlan
-----+-----+-----+-----+-----+-----+-----+-----+
Et38 access notconnect 1 1 0 ---
```

### 21.1.12.36 switchport tool allowed vlan

The **switchport tool allowed vlan** command creates or modifies the list of VLANs for which the configuration-mode interface, in tool mode, handles tagged traffic. By default, interfaces handle tagged traffic for all VLANs. Command settings persist in ***running-config*** without taking effect when the switch is not in TAP aggregation mode or the interface is not in TAP aggregation mode.

The **no switchport tool allowed vlan** and **default switchport tool allowed vlan** commands restore the tool mode default allowed VLAN setting of **all** by removing the corresponding **switchport tool allowed vlan** statement from ***running-config***.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

**switchport tool allowed vlan** **EDIT\_ACTION**

#### Parameters

**EDIT\_ACTION** modifications to the VLAN list. Options include:

- **v\_range** creates VLAN list from **v\_range**.
- **add v\_range** adds specified VLANs to current list.
- **all** VLAN list contains all VLANs.
- **except v\_range** VLAN list contains all VLANs except those specified.
- **none** VLAN list is empty (no VLANs).
- **remove v\_range** removes specified VLANs from current list.

Valid **v\_range** formats include number, range, or comma-delimited list of numbers and ranges.

#### Example

These commands create the tool mode allowed VLAN list of **16-20** for **interface ethernet 38**.

```
switch(config)# interface ethernet 38
switch(config-if-Et38)# switchport tool allowed vlan 16-20
switch(config-if-Et38)# show interfaces ethernet 38 tool
Port Configured Status Allowed Id Timestamp
Mode Mode Vlans Tag Mode

Et38 access notconnect 16-20 Off None
switch(config-if-Et38)#

```

### 21.1.12.37 switchport tool group

The **switchport tool group** command modifies the configuration-mode interface's tool port membership in the specified TAP aggregation groups. Tool ports may belong to multiple TAP aggregation groups. Command options for configuring a port's TAP aggregation group membership include:

- specifying the groups to which the port belongs (supersedes the port's previous group memberships).
- adding to the list of groups to which the port belongs.
- deleting from the list of groups to which the port belongs.

TAP aggregation groups associate a set of TAP ports with a set of tool ports. A TAP port can belong to a maximum of one default TAP aggregation group.

The **no switchport tool default group** and **default switchport tool default group** commands remove the configuration-mode interface from all TAP aggregation groups to which it is assigned as a tool port by modifying the corresponding statements in **running-config**.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

**switchport tool group EDIT\_ACTION**

#### Parameters

**EDIT\_ACTION** specifies changes to the list of groups to which the port belongs.

- **add group\_list** specifies additional groups to which the port belongs.
- **remove group\_list** removes interface as a tool port member from specified groups.
- **set group\_list** specifies groups to which interface belongs as a tool port.

Valid **group\_list** format is a space-delimited list of one or more TAP aggregation group names.

#### Restriction

This command is available only on FM6000 platform switches.

#### Examples

- These commands associate **interface ethernet 40** with three TAP aggregation groups.

```
switch(config)# interface ethernet 40
switch(config-if-Et40)# switchport tool group set tag-1 tag-2 tag-3
switch(config-if-Et40)# show active
interface Ethernet40
 switchport tool group set tag-3 tag-2 tag-1
switch(config-if-Et40) #
```

- These commands add **tag-7** to the tap aggregation groups to which **interface ethernet 40** belongs.

```
switch(config-if-Et40)# switchport tool group add tag-7
switch(config-if-Et40)# show active
interface Ethernet40
 switchport tool group set tag-3 tag-7 tag-2 tag-1
switch(config-if-Et40) #
```

- These commands specify **tag-9** as the only group to which **interface ethernet 40** belongs.

```
switch(config-if-Et40)# switchport tool group set tag-9
```

```
switch(config-if-Et40)# show active
interface Ethernet40
 switchport tool group set tag-9
switch(config-if-Et40)#[/pre>
```

---

### 21.1.12.38 switchport tool identity

The **switchport tool identity** command configures the configuration-mode interface to add a tier-1 VLAN tag (dot1q) to packets it receives from TAP ports. The VLAN number on the dot1q tag is specified by the **switchport tap identity** command configured for the TAP port that supplies the packets. By default, tool ports do not encapsulate packets with the tier-1 VLAN tag.

The **no switchport tool identity** and **default switchport tool identity** commands restore the default VLAN handling method for the configuration-mode interface by removing the corresponding **switchport tool identity** statement from *running-config*.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

```
switchport tool identity dot1q
no switchport tool identity dot1q
default switchport tool identity dot1q
```

#### Restriction

This command is available only on FM6000 platform switches.

#### Example

These commands configure **interface ethernet 40** to include a dot1q tag on egress packets.

```
switch(config)# interface ethernet 40
switch(config-if-Et40)# switchport tool identity dot1q
switch(config-if-Et40)# show active
interface Ethernet40
 switchport mode tool
 switchport tool identity dot1q
 switchport tool group set tag-9
switch(config-if-Et40)#[/pre]
```

### 21.1.12.39 switchport tool truncation

The **switchport tool truncation** command configures the configuration-mode interface, as a tool port, to truncate outbound packets to **160** bytes. This command is in effect when the port is in tool mode and the switch is in TAP aggregation mode. Command settings persist in ***running-config*** without taking effect when the switch is not in TAP aggregation mode or the interface is not in tool mode. By default, tool ports do not truncate outbound packets.

The **no switchport tool truncation** and **default switchport tool truncation** commands restore the default behavior (not truncating packets that exit the configuration mode interface) by removing the corresponding **switchport tool truncation** command from ***running-config***.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

#### Command Syntax

```
switchport tool truncation packet_size
no switchport tool truncation
default switchport tool truncation
```

#### Parameter

***packet\_size*** size of truncated packets in bytes. The only permitted value is **160**.

#### Examples

- These commands configure **interface ethernet 38**, as a tool port, to truncate packets on egress to **160** bytes.

```
switch(config)# interface ethernet 38
switch(config-if-Et38)# switchport mode tool
switch(config-if-Et38)# switchport tool truncation 160
switch(config-if-Et38) #
```

- These commands configure **interface ethernet 38** to send complete packets.

```
switch(config)# interface ethernet 38
switch(config-if-Et38)# no switchport tool truncation
switch(config-if-Et38) #
```

## 21.1.12.40 tap aggregation

The **tap aggregation** command places the switch in TAP-aggregation configuration mode. The switch's TAP aggregation mode is enabled or disabled by the [mode \(tap-agg configuration mode\)](#) command in TAP-aggregation configuration mode.

When TAP aggregation mode is enabled, normal switching and routing operations are disabled. A port's switchport status depends on the switch's TAP aggregation mode and the port's switchport mode:

- **TAP aggregation mode enabled:** TAP and tool ports are enabled. Switching ports are errdisabled.
- **TAP aggregation mode disabled:** TAP and tool ports are errdisabled. Switching ports are enabled.

The **no tap aggregation** and **default tap aggregation** commands disable tap aggregation mode on the switch by removing all TAP-aggregation configuration mode commands from **running-config**.

TAP-aggregation configuration mode is not a group-change mode; **running-config** is changed immediately upon entering commands. Exiting TAP-aggregation configuration mode does not affect **running-config**. The **exit** command returns the switch to global configuration mode.

### Command Mode

Global Configuration

### Command Syntax

```
tap aggregation
no tap aggregation
default tap aggregation
```

### Commands Available in TAP-aggregation Configuration Mode

[mode \(tap-agg configuration mode\)](#)

### Related Command

[switchport mode](#)

### Examples

- These commands place the switch in TAP-aggregation configuration mode and enable TAP aggregation.

```
switch(config)# tap aggregation
switch(config-tap-agg)# mode exclusive
switch(config-tap-agg)# show active
tap aggregation
 mode exclusive
switch(config-tap-agg) #
```

- You can apply a Tap Aggregation profile globally under the tap aggregation configuration using the mode exclusive profile command. With this command, the tap aggregation profile will be applied to tap aggregation line cards.

```
switch(config)# tap aggregation
switch(config-tap-agg)# mode exclusive profile profilename
```

- This command disables TAP aggregation and removes all TAP-aggregation configuration mode commands from **running-config**.

```
switch(config)# no tap aggregation
switch(config) #
```

## 21.2 Latency Analyzer (LANZ)

Arista Networks' Latency Analyzer (LANZ) is a family of EOS features that provide enhanced visibility into network dynamics, particularly in areas related to the delay packets experience through the network. The LANZ feature is available on the FM6000, Arad, Trident II, Trident 3, Jericho, Tomahawk, and XP80 switch platforms.

This section describes the purpose, behavior, and configuration of LANZ features. Topics covered by this section include:

- [Introduction to LANZ](#)
- [LANZ Overview](#)
- [Configuring LANZ](#)
- [LANZ Commands](#)

### 21.2.1 Introduction to LANZ

LANZ tracks interface congestion and queuing latency with real-time reporting. With LANZ application layer event export, external applications can predict impending congestion and latency. This enables the application layer to make traffic routing decisions with visibility into the network layer.

With LANZ, network operations teams and administrators have near real-time visibility into the network, enabling early detection of microbursts. LANZ continually monitors congestion, allowing for rapid congestion detection and sending of application layer messages.

### 21.2.2 LANZ Overview

LANZ monitors output queue lengths to provide congestion information for individual interfaces. This allows for detailed analysis of congestion events and identification of potential latency problems before they arise. On some platforms, LANZ also monitors global buffer usage.

Output queues for each port are monitored, and information about queue congestion events can be accessed in the form of system log messages, reports, or streaming.

#### 21.2.2.1 LANZ Monitoring Mechanism

LANZ provides congestion data by continuously monitoring each port's output queue lengths. When the length of an output queue exceeds the upper threshold for that port, LANZ generates an over-threshold event.

##### 21.2.2.1.1 Notifying and Polling Modes

###### Notifying Mode

In Notifying Mode (available on all platforms), LANZ monitors congestions on all queues and generates Start, Update, and End events every five seconds or at user-configured intervals.

- **Start** event is generated when any queue on an interface exceeds the upper threshold.
- **Update** events are generated periodically while the congested queue remains above the lower threshold. The interval at which Update events are generated is configured using the [queue-monitor length update-interval](#) command.
- **End** event is generated when the congested queue drops below the lower threshold.

---

### **Polling Mode**

Polling Mode is available only on Arad and Jericho switches. On these switches, LANZ can be configured to use Notifying Mode, but it operates in Polling Mode by default. In Polling Mode, LANZ polls the most congested queue in each ASIC and continues to report an over-threshold state every **800** microseconds until all queue lengths for the port pass below the lower threshold.

#### **21.2.2.2 LANZ Logging**

Over-threshold events generated by LANZ can be logged as system log messages. Log messages are generated for events on all ports at a maximum rate of one message per second per interface. You can configure the interval between messages globally.

Log messages indicate the time of the event, the interface affected, the threshold set for that interface, and the number of entries in the port's queue.

#### **21.2.2.3 LANZ Reporting**

You can view detailed LANZ data through the CLI or export it as a CSV-formatted report.

All interfaces dynamically share a circular FIFO event buffer. When an interface generates LANZ over-threshold events, it can fill all available buffer space. However, each interface is guaranteed sufficient resources for a minimum of 500 entries.

#### **21.2.2.4 LANZ Streaming**

On some platforms, external client applications can also receive congestion event information as a data stream. The switch can stream LANZ data to up to 100 clients via TCP through port 50001.

Streamed data is in Google protocol buffer format and includes both over-threshold events and LANZ configuration information.

### **21.2.3 Configuring LANZ**

LANZ is disabled by default and must be enabled to function. You can define upper and lower queue-length thresholds for individual interfaces.

These sections describe the basic LANZ configuration steps:

- [Enabling and Disabling LANZ](#)
- [Specifying the LANZ Mode on Jericho and Arad Switches](#)
- [Configuring LANZ Congestion Thresholds](#)
- [Setting LANZ Traffic Sampling](#)
- [Logging LANZ Congestion Events](#)
- [Viewing LANZ Data](#)
- [Streaming LANZ Data](#)

#### **21.2.3.1 Enabling and Disabling LANZ**

LANZ is enabled by default on Sand platform switches (those with Arad, Jericho, or Qumran chipsets), allowing the switch to collect and display latency information. LANZ is disabled by default on all other

switches. If LANZ is disabled, the [queue-monitor length \(global configuration mode\)](#) command enables LANZ with the current settings, or with the default settings if none have been configured.

When LANZ is enabled, the switch monitors queue lengths on all front-panel ports and on CPU and fabric ports on selected platforms. Queue length data is available in the following forms:

- syslog data (see [queue-monitor length log](#))
- CLI display or CSV-format output (see [show queue-monitor length](#))
- data stream (see [queue-monitor streaming](#))

To disable LANZ globally, enter the `no queue-monitor length` command in global configuration mode. Disabling LANZ globally also discards LANZ log data, but retains settings. To disable LANZ on an individual interface, enter the `no queue-monitor length` command in interface Ethernet configuration mode.

### Examples

- This command enables LANZ on the switch.

```
switch(config)# queue-monitor length
switch(config)#{}
```

- This command disables LANZ on the switch.

```
switch(config)# no queue-monitor length
switch(config)#{}
```

- These commands disable LANZ on Ethernet interface 7.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# no queue-monitor length
switch(config-if-Et7)#{}
```

#### 21.2.3.2 Specifying the LANZ Mode on Jericho and Arad Switches

On Jericho and Arad switches, LANZ operates by default in Polling Mode, which provides congestion data for the most congested queue per ASIC. They also support Notifying Mode (the LANZ mode used on all other switches), which generates Start, Update, and End events for all queues.

Notifying Mode is enabled using the [queue-monitor length notifying](#) command.

### Examples

- This command enables Notifying Mode on a Jericho or Arad switch.

```
switch(config)# queue-monitor length notifying
```

- This command disables Notifying Mode on a Jericho or Arad switch, returning LANZ to the default Polling Mode.

```
switch(config)# no queue-monitor length notifying
```

#### 21.2.3.3 Configuring LANZ Congestion Thresholds

When LANZ is enabled on the switch, it generates over-threshold events when queue lengths on any monitored interface exceed the upper threshold value and continues generating them until all the queue lengths on that interface drop back below the lower threshold.

### 21.2.3.3.1 Setting the Congestion Update Interval

The [queue-monitor length update-interval](#) command specifies the frequency with which congestion information is updated in microseconds.

- This command sets the time between congestion updates to **10** seconds.

```
switch(config)# queue-monitor length update-interval 10000000
switch(config) #
```

- This command resets the time between congestion updates to its default value of **5** seconds.

```
switch(config)# default queue-monitor length update-interval
switch(config) #
```

### 21.2.3.3.2 Congestion Thresholds on FM6000, Trident II, Trident 3, and Tomahawk Switches

Queue lengths are measured in 480-byte segments on FM6000 switches, in 208-byte segments on Trident II and Tomahawk switches, and in 256-byte segments on Trident 3 switches. The default threshold values are **512** segments and **256** segments. To change the threshold values for a specific interface, use the [queue-monitor length thresholds](#) command.

FM6000 switches can also monitor global buffer usage. Global buffers are measured in 160-byte segments; the default threshold values are **10940** segments and **4376** segments. To enable global buffer monitoring, use the [queue-monitor length global-buffer](#) command. To change the threshold values for global buffer usage monitoring on the switch, use the [queue-monitor length global-buffer thresholds](#) command.

#### Examples

- These commands set the upper and lower queue-length thresholds on *interface ethernet 5* to 300 segments and 200 segments.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# queue-monitor length thresholds 300 200
switch(config-if-Et5) #
```

- These commands enable global buffer monitoring on the switch and set the upper and lower thresholds to 9000 segments and 4000 segments.

```
switch(config)# queue-monitor length global-buffer
switch(config)# queue-monitor length global-buffer thresholds 9000 4000
switch(config) #
```

### 21.2.3.3.3 Congestion Thresholds on Arad Switches

Queue lengths are measured in bytes. The top threshold value can be between **2** and **52428800** bytes (the default value is **52428800** bytes). To change the upper threshold value for a specific interface, use the [queue-monitor length threshold \(Arad/Jericho/Qumran\)](#) command.

#### Example

These commands set the upper queue-length threshold on *interface ethernet 5* to **2614400** bytes.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# queue-monitor length thresholds 2614400
switch(config-if-Et5) #
```

#### 21.2.3.3.4 CPU Port Congestion Thresholds

CPU port queue lengths are also monitored on selected platforms. All CPU ports share common threshold values, which are configured using the [queue-monitor length cpu thresholds](#) command. Individual CPU port congestion thresholds cannot be separately configured.

##### Examples

- This command sets the upper queue-length threshold for congestion monitoring on all CPU ports to **1000** segments and the lower limit to **300** segments.

```
switch(config)# queue-monitor length cpu thresholds 1000 300
switch(config)#

```

- This command resets the queue-length thresholds for CPU port congestion to the default values of **512** and **256**.

```
switch(config)# default queue-monitor length cpu thresholds
switch(config)#

```

#### 21.2.3.3.5 Fabric Port Congestion Thresholds

Fabric port queue lengths are also monitored on selected platforms. All fabric ports share common threshold values, which are configured using the [queue-monitor length fabric thresholds](#) command. You cannot configure individual fabric port congestion thresholds separately.

##### Examples

- This command sets the upper queue-length threshold for congestion monitoring on all fabric ports to **1000** segments and the lower limit to **300** segments.

```
switch(config)# queue-monitor length fabric thresholds 1000 300
switch(config)#

```

- This command resets the queue-length thresholds for fabric port congestion to the default values of **512** and **256**.

```
switch(config)# default queue-monitor length fabric thresholds
switch(config)#

```

#### 21.2.3.4 Setting LANZ Traffic Sampling

To configure the switch to automatically send congested traffic to either the CPU or an Ethernet egress interface destination when congestion crosses a queue threshold, enable LANZ mirroring through the [queue-monitor length mirror](#) command, then configure the CPU or an egress interface mirror destination to receive the mirrored packets using the [queue-monitor length mirror destination](#) command. LANZ traffic sampling includes exporting congested traffic to a packet-capture device or another tool for analysis or directly to the switch CPU for inspection through the [tcpdump queue-monitor](#) command.

##### Examples

- This command enables LANZ traffic sampling.

```
switch(config)# queue-monitor length mirror

```

```
switch(config) #
```

- This command disables LANZ traffic sampling.

```
switch(config) # no queue-monitor length mirror
switch(config) #
```

- This command configures EOS to send LANZ traffic samples to a CPU.

```
switch(config) # queue-monitor length mirror destination cpu
switch(config) #
```

- This command configures EOS to send LANZ traffic samples to ports **1** through **5**.

```
switch(config) # queue-monitor length mirror destination Ethernet 1-5
switch(config) #
```

- This command configures EOS to send LANZ traffic samples to ports **6**, **10**, and **12** through **14**.

```
switch(config) # queue-monitor length mirror destination Ethernet 6,10,12-14
switch(config) #
```

- This command inspects traffic on the switch.

```
switch(config) # tcpdump queue-monitor
tcpdump: WARNING: lanz: no IPv4 address assigned
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on lanz, link-type EN10MB (Ethernet), capture size 65535 bytes
...
0 packets captured
0 packets received by filter
0 packets dropped by kernel
switch(config) #
```

### 21.2.3.5 Logging LANZ Congestion Events

To generate syslog messages when queue lengths on an interface exceed its upper threshold, enable logging with the [queue-monitor length log](#) command. When logging is enabled, LANZ generates a log message each time one or more queues on an interface exceed the upper threshold value for that interface (see [queue-monitor length threshold \(Arad/Jericho/Qumran\)](#) or [queue-monitor length thresholds](#)). When an interface is over-threshold, additional messages are generated at a maximum rate of one per interval as long as the queue length remains above the lower threshold for that interface. LANZ does not generate a syslog message when the queue length drops back below the threshold.

Queue length information is not included in log messages, but you can access it by displaying LANZ data or exporting reports.

On FM6000 platforms, you can also configure LANZ to generate log messages whenever global buffer usage exceeds its upper threshold value (see [queue-monitor length global-buffer thresholds](#)). To enable global buffer monitoring, use the [queue-monitor length global-buffer](#) command. To log over-threshold events for the global buffer, use the [queue-monitor length global-buffer log](#) command.

### Examples

- This command enables queue-length over-threshold logging with a minimum interval of **10** seconds between messages for a given interface.

```
switch(config) # queue-monitor length log 10
```

- This command turns off queue-length over-threshold logging on the switch.

```
switch(config)# queue-monitor length log 0
```

- This is an example of a queue-length log message.

```
Oct 27 12:48:22 switch QUEUE_MONITOR-6-LENGTH_OVER_THRESHOLD: Interface
Ethernet6 queue length is over threshold of 512, current length is 1024.
```

- This command enables global buffer over-threshold logging on the switch with a minimum interval of **60** seconds between messages.

```
switch(config)# queue-monitor length global-buffer log 60
```

## 21.2.3.6 Viewing LANZ Data

LANZ status and the data stored in the LANZ data buffer can be viewed using the CLI. Output varies by switch platform and can be limited to a specified number of records.

### 21.2.3.6.1 Viewing LANZ Data on Arad Platform Switches

When LANZ is enabled on an Arad platform switch, the [show queue-monitor length](#) command displays a report of recent over-threshold events for a range of interfaces or for all interfaces. By default, the command displays data for all interfaces, limited to the last 1000 records, with the most recent events listed first. Use the [show queue-monitor length limit](#) command to view a subset of the LANZ data limited to a specified number of records.

#### Example

This command displays the last **100** records for Ethernet interfaces **6** through **8**.

```
switch# show queue-monitor length ethernet 6-8 limit 100
Report generated at 2010-01-01 12:56:13

Time Interface Queue length (segments, 1 to 512 bytes)

0:00:07.43393 ago Et6 1049
0:00:39.22856 ago Et7 2039
1 day, 4:33:23.12345 ago Et6 1077
```

To view the current LANZ configuration for the switch and for each interface, use the [show queue-monitor length status](#) command.

#### Example

This command displays LANZ configuration and status information.

```
switch(config)# show queue-monitor length status
Per-Interface Queue Length Monitoring

Queue length monitoring is enabled
Maximum queue length in bytes : 52428800
Port threshold in bytes:
Port High threshold
Et3/1 5242880
Et3/2 5242880
Et3/3 5242880
Et3/4 5242880
Et3/5 5242880
```

### 21.2.3.6.2 Viewing LANZ Data on FM6000, Trident II, Trident 3, and Tomahawk Platform Switches

When LANZ is enabled on an FM6000, Trident II, Trident 3, or Tomahawk platform switch, the [show queue-monitor length](#) command displays a report of recent over-threshold events for a range of interfaces or for all interfaces. By default, the command displays data for all interfaces, limited to the last **1000** records, with the most recent events listed first. To view a subset of the LANZ data limited to a specified number of records, use the [show queue-monitor length limit](#) command.

#### Example

This command displays the last **100** records for Ethernet interfaces **6** through **8**.

```
switch# show queue-monitor length ethernet 6-8 limit 100
Report generated at 2010-01-01 12:56:13

Time Interface Queue length (segments, 1 to 512 bytes)

0:00:07.43393 ago Et6 1049
0:00:39.22856 ago Et7 2039
1 day, 4:33:23.12345 ago Et6 1077
```

To view the current LANZ configuration for the switch and for each interface, use the [show queue-monitor length status](#) command.

#### Example

This command displays LANZ configuration and status information.

```
switch(config)# show queue-monitor length status
queue-monitor length enabled
Global Buffer Monitoring

Global buffer monitoring is enabled
Segment size in bytes : 160
Total buffers in segments : 36864
High threshold : 10940
Low threshold : 4376

Per-Interface Queue Length Monitoring

Queue length monitoring is enabled
Segment size in bytes : 480
Maximum queue length in segments : 3647
Port thresholds in segments:
Port High threshold Low threshold
Et1 512 256
Et2 512 256
Et3 512 256
Et4 512 256
Et5 512 256
```

To view all available LANZ records, use the [show queue-monitor length all](#) command.

#### Example

This command displays all available LANZ records.

```
switch> show queue-monitor length all
Report generated at 2013-04-01 13:23:13
E-End, U-Update, S-Start, TC-Traffic Class
GH-High, GU-Update, GL-Low
Segment size for E, U and S congestion records is 480 bytes
Segment size for GL, GU and GH congestion records is 160 bytes
* Max queue length during period of congestion
+ Period of congestion exceeded counter
```

| Type | Time                      | Intf<br>(TC) | Congestion<br>duration<br>(usecs) | Queue<br>length<br>(segments) | Time of Max<br>Queue length<br>relative to<br>congestion<br>start<br>(usecs) |
|------|---------------------------|--------------|-----------------------------------|-------------------------------|------------------------------------------------------------------------------|
| E    | 0:00:00.07567 ago         | Et22(7)      | >=71 mins                         | 20*                           | 30us                                                                         |

| U    | 0:00:03.08248 ago         | Et44(1)      | N/A                               | 50                            | N/A                                                                          |
| S    | 12days, 8:56:44.07567 ago | Et44(1)      | N/A                               | 20                            | N/A switch>                                                                  |

On the FM6000, Trident II, Trident 3, and Tomahawk platforms, information is also available for the number of dropped packets (see [show queue-monitor length drops](#)) and transmission latency (see [show queue-monitor length tx-latency](#)); global buffer usage can also be viewed on FM6000 platforms (see [show queue-monitor length global-buffer](#)).

### 21.2.3.7 Streaming LANZ Data

You can configure the switch to stream LANZ congestion and configuration data to support analysis of latency conditions. The switch streams LANZ data via TCP in Google protocol buffer format through port 50001 and through the management interface.

You must create a client application to receive the streaming data. By default, the switch will accept up to 10 client connections for streaming LANZ data. LANZ data. You can configure this limit up to a maximum of 100. Maximum connections can be configured when LANZ is disabled.

#### 21.2.3.7.1 Enabling and Disabling LANZ Data Streaming

LANZ data streaming is disabled by default. To enable streaming, issue the `no show queue-monitor streaming clients` command in queue-monitor streaming configuration mode. To disable streaming, use the `show queue-monitor streaming clients` command.

When streaming is disabled, LANZ sends a message to any connected clients, and the connections are closed.

To ensure client access to LANZ data, add a rule to any relevant ACL permitting traffic destined for the LANZ port (**50001**) before initiating a client connection for streaming from a remote host. A static rule (sequence number **130**) in the default control plane ACL permits LANZ traffic, but you must add a similar rule to any user-created ACL.

#### Examples

- These commands enable the streaming of LANZ data from the switch.

```
switch(config)# queue-monitor streaming
switch(config-qm-streaming)# no shutdown
switch(config-qm-streaming)#

```

- These commands disable LANZ data streaming.

```
switch(config)# queue-monitor streaming
switch(config-qm-streaming)# shutdown
switch(config-qm-streaming)#

```

### 21.2.3.7.2 Configuring Maximum Connections

By default, the switch will accept a maximum of **10** client connections for LANZ data streaming. You can configure this maximum using the **max-connections** command. If a client connects to the switch after the limit has been reached, an error message is sent and the connection is closed.

#### Example

This command sets the maximum number of client connections for LANZ data streaming to **50**.

```
switch(config-qm-streaming) # max-connections 50
```

### 21.2.3.7.3 LANZ Streaming Messages

When streaming is enabled, LANZ sends a message whenever a congestion event or a configuration event occurs. The messages are streamed in Google protocol buffer format.

#### Configuration Messages

LANZ sends a configuration message whenever a change is made to the LANZ configuration settings on the switch. The switch also sends a configuration message when a new client connection is established.

The configuration message includes the following information:

- **timestamp** time of change in configuration in tens of microseconds (UTC).
- **lanzVersion** LANZ feature version.
- **numOfPorts** number of ports in the switch.
- **segmentSize** segment size.
- **maxQueueSize** maximum queue size in segments.
- **qLenInterval** frequency of updates.
- **intfName** name of the port.
- **switchId** ID of the chip on a multi-chip system.
- **portId** ID of the port.
- **internalPort** “true” if it is an internal port.
- **highThreshold** higher threshold value.
- **lowThreshold** lower threshold value.

#### Congestion Messages

LANZ sends a congestion message whenever it generates an over-threshold event.

The congestion message includes the following information:

- **timestamp** time of congestion in micro-seconds (UTC).
- **intfName** name of the port.
- **switchId** ID of the chip on a multi-chip system.
- **portId** ID of the port.
- **queueSize** queue size in segments at time of congestion.

#### 21.2.3.7.4 Creating the LANZ Client

For a client device to receive streaming data from the LANZ server, it must be running a client application designed to receive LANZ data. Client programs must be based on the Google protocol buffer schema file describing the structure of the congestion and configuration messages that LANZ streams.

##### Google Protocol Buffers

Google protocol buffers provide an efficient mechanism for serializing LANZ data for streaming. A protocol buffer package is needed to run a LANZ client.

The latest version of the Google protocol buffer source code is available at this address: <https://github.com/protocolbuffers/protobuf>

##### LANZ Message Schema

LANZ client applications must be designed based on the LANZ protocol buffer schema, which defines the format and contents of the streamed messages. The schema file is shown below, and is also available in the Extensions/LANZ directory on this page: <https://www.arista.com/en/support/software-download>

```
package LanzProtobuf;

message ConfigRecord {
 required uint64 timestamp = 1; // Time of change in configuration in
 micro-seconds (UTC)
 required uint32 lanzVersion = 2; // LANZ feature version
 required uint32 numofPorts = 3; // Num of ports in the switch
 required uint32 segmentSize = 4; // Segement size
 required uint32 maxQueueSize = 5; // Maximum queue size in segments
 optional uint32 qLenInterval = 10; // Frequency of update
 message PortConfigRecord {
 required string intfName = 1; // Name of the port
 required uint32 switchId = 2; // Id of the chip on a multi-chip system
 required uint32 portId = 3; // Id of the port
 required bool internalPort = 4; // 'True' if it's an internal port
 required uint32 highThreshold = 5; // Higher threshold
 required uint32 lowThreshold = 6; // Lower threshold
 }
 repeated PortConfigRecord portConfigRecord = 6; // Lanz config details of each
 port
}

message CongestionRecord {
 required uint64 timestamp = 1; // Time of congestion in micro-seconds
 (UTC)
 required string intfName = 2; // Name of the port
 required uint32 switchId = 3; // Id of the chip on a multi-chip system
 required uint32 portId = 4; // Id of the port
 required uint32 queueSize = 5; // Queue size in segments at time of
 congestion
}

message ErrorRecord {
 required uint64 timestamp = 1; // Time of event in micro-seconds (UTC)
 required string errorMessage = 2; // Text message
}

message LanzRecord {
 optional ConfigRecord configRecord = 1;
 optional CongestionRecord congestionRecord = 2;
 optional ErrorRecord errorRecord = 3;
}
```

##### Implementation Procedure

The following steps create and install a functional client to receive streamed LANZ data. This procedure assumes a functional Python programming environment.

1. Download the example client (`lanz_client.py`) from the Arista website. It is available in the Extensions/LANZ directory on this page: <https://www.arista.com/en/support/software-download>

- 
- 2.** Decompress the GPB archive to a directory.
  - 3.** Run the GPB C++ compilation and install. With default flags using GNU Compiler Collection (GCC) on \*nix platforms, this will produce a binary called **protoc** in your **/usr/local/bin** directory.
  - 4.** From the archive root, **cd** to python, and run the following commands:
    - **python setup.py build**
    - **python setup.py tests**
  - 5.** Next, use the protoc compiler to convert the Lanz.proto file into a Python program called Lanz\_pb2.py, used by the client. The command to do so is:
    - **protoc --python\_out=. Lanz.proto**
    - The **--python\_out=.** flag drops the compiled Python program in the directory where you ran the command.
  - 6.** Run **lanz\_client.py -h** to activate the LANZ client.

## 21.2.4 LANZ Commands

### LANZ Commands: Global Configuration

- clear queue-monitor length statistics
- queue-monitor length (global configuration mode)
- queue-monitor length cpu thresholds
- queue-monitor length fabric thresholds
- queue-monitor length global-buffer
- queue-monitor length global-buffer log
- queue-monitor length global-buffer thresholds
- queue-monitor length log
- queue-monitor length mirror
- queue-monitor length mirror destination
- queue-monitor length notifying
- queue-monitor length update-interval
- queue-monitor streaming
- tcpdump queue-monitor

### LANZ Commands: Interface Ethernet Configuration Mode

- queue-monitor length threshold (Arad/Jericho/Qumran)
- queue-monitor length thresholds

### LANZ Commands: Queue-Monitor Streaming Configuration Mode

- max-connections
- shutdown (queue-monitor-streaming configuration)

### LANZ Display Commands

- show queue-monitor length
- show queue-monitor length all
- show queue-monitor length cpu
- show queue-monitor length csv
- show queue-monitor length drops
- show queue-monitor length ethernet
- show queue-monitor length global-buffer
- show queue-monitor length limit
- show queue-monitor length statistics
- show queue-monitor length status
- show queue-monitor length tx-latency
- show queue-monitor streaming clients

---

#### **21.2.4.1 clear queue-monitor length statistics**

The **clear queue-monitor length statistics** command resets the occurrences of all over-threshold events on the switch, including global buffer information (if supported).

##### **Command Mode**

Privileged EXEC

##### **Command Syntax**

```
clear queue-monitor length statistics
```

##### **Example**

This command resets all over-threshold events and global buffer information on an FM6000 switch.

```
switch# clear queue-monitor length statistics
switch#
```

#### 21.2.4.2 max-connections

The max-connections command sets the maximum number of client connections the switch accepts for streaming LANZ data. The default maximum is 10 connections. To stream LANZ data, you must use the [queue-monitor streaming](#) command to enable LANZ data streaming.

##### Command Mode

Queue-Monitor-Streaming Configuration

##### Command Syntax

```
max-connections connections
```

##### Parameter

***connections*** maximum number of simultaneous LANZ streaming client connections the switch will accept. Values range from **1** through **100**.

##### Example

This command sets the maximum number of client connections the switch accepts for LANZ data streaming to **50**.

```
switch(config-qm-streaming)# max-connections 50
switch(config-qm-streaming) #
```

#### 21.2.4.3 queue-monitor length (global configuration mode)

The `queue-monitor length (global configuration mode)` command enables LANZ with the current settings, or with the default settings if LANZ has not yet been configured. LANZ is enabled by default on Sand platform switches (those with Arad, Jericho, or Qumran chipsets) and disabled by default on all other switches.

When LANZ is enabled, the switch monitors queue lengths on all ports and generates over-threshold events when an output queue becomes congested. Over-threshold event data is available in the following forms:

- syslog data (see [queue-monitor length log](#)).
- CLI display or CSV-format output (see [show queue-monitor length](#)).
- data stream (see [queue-monitor streaming](#)).

The `no queue-monitor length` command entered in global configuration mode disables LANZ and discards LANZ log data, but retains settings. LANZ settings include:

- logging settings (see [queue-monitor length log](#)).
- queue length thresholds (see [queue-monitor length threshold \(Arad/Jericho/Qumran\)](#) or [queue-monitor length thresholds](#)).
- data streaming settings (see [queue-monitor streaming](#)).

To disable LANZ on an interface, use the `no queue-monitor length` command in interface configuration mode.

#### Command Mode

Global Configuration

#### Command Syntax

```
queue-monitor length
no queue-monitor length
default queue-monitor length
```

#### Examples

- This command enables LANZ on the switch.

```
switch(config)# queue-monitor length
switch(config)#
```

- This command disables LANZ on the switch and discards LANZ data but maintains configurations.

```
switch(config)# no queue-monitor length
switch(config)#
```

- This command disables LANZ on Ethernet interface 3/30.

```
switch(config)# interface ethernet 3/30
switch(config-if-Et3/30)# no queue-monitor length
switch(config-if-Et3/30)#
```

#### 21.2.4.4 queue-monitor length cpu thresholds

The `queue-monitor length cpu thresholds` command sets the queue length threshold to define “congested” on all CPU ports for purposes of LANZ reporting. If LANZ is enabled (see [queue-monitor length \(global configuration mode\)](#)), an over-threshold event is generated when one or more queues on a CPU interface exceed the upper threshold, and over-threshold events continue to be generated until all queue lengths on the interface drop below the lower threshold. (To log these events, use the [queue-monitor length log](#) command.) Different monitoring thresholds cannot be set for individual CPU ports.

The `no queue-monitor length cpu thresholds` and `default queue-monitor length cpu thresholds` commands reset thresholds to the default values (high: **512** segments; low: **256** segments).

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor length cpu thresholds [upper_limit | lower_limit]
no queue-monitor length cpu thresholds
default queue-monitor length cpu thresholds
```

##### Parameters

- ***upper\_limit*** is the queue length in segments that triggers an over-threshold event. Values range from **8** to **16382**. Default setting is **512**. Segment size varies by platform.
- ***lower\_limit*** When logging is enabled, an over-threshold interface continues generating over-threshold events until all its queues drop back below this length. Must be lower than ***upper\_limit***. Values range from **1** to **16382**. Default setting is **256**.

##### Examples

- This command sets the upper queue-length threshold for congestion monitoring on all CPU ports to **1000** segments and the lower limit to **300** segments.

```
switch(config)# queue-monitor length cpu thresholds 1000 300
switch(config)#
```

- This command resets the queue-length thresholds for CPU port congestion to the default values of **512** and **256**.

```
switch(config)# default queue-monitor length cpu thresholds
switch(config)#
```

## 21.2.4.5 queue-monitor length fabric thresholds

The `queue-monitor length fabric thresholds` command sets the `queue-monitor length thresholds` to define “congested” on all fabric ports for purposes of LANZ reporting. If LANZ is enabled (see `queue-monitor length` (global configuration mode)), an over-threshold event is generated when one or more queues on a fabric interface exceed the upper threshold, and over-threshold events continue to be generated until all queue lengths on the interface drop below the lower threshold. (To log these events, use the `queue-monitor length log` command.) Different monitoring thresholds cannot be set for individual fabric ports.

The `no queue-monitor length fabric thresholds` and `default queue-monitor length fabric thresholds` commands reset thresholds to the default values (high: **512** segments; low: **256** segments).

### Command Mode

Global Configuration

### Command Syntax

```
queue-monitor length fabric thresholds [upper_limit | lower_limit]
no queue-monitor length fabric thresholds
default queue-monitor length fabric thresholds
```

### Parameters

- ***upper\_limit*** is the queue length in segments that triggers an over-threshold event. Values range from **8** to **16382**. Default setting is **512**. Segment size varies by platform.
- ***lower\_limit*** When logging is enabled, an over-threshold interface continues generating over-threshold events until all its queues drop back below this length. Must be lower than ***upper\_limit***. Values range from **1** to **16382**. Default setting is **256**.

### Examples

- This command sets the upper queue-length threshold for congestion monitoring on all fabric ports to **1000** segments and the lower limit to **300** segments.

```
switch(config)# queue-monitor length fabric thresholds 1000 300
switch(config)#{}
```

- This command resets the queue-length thresholds for fabric port congestion to the default values of **512** and **256**.

```
switch(config)# default queue-monitor length fabric thresholds
switch(config)#{}
```

#### 21.2.4.6 queue-monitor length global-buffer log

The `queue-monitor length global-buffer log` command enables logging of global buffer over-threshold events. When logging is enabled, a log message is generated each time the contents of the global buffer exceed the upper threshold value set for the switch (see [queue-monitor length global-buffer thresholds](#)). Once the global buffer is over the threshold, additional messages are generated at a maximum rate of one per interval as long as the buffer value remains above the lower threshold for the switch.

Global buffer logging is disabled by default.

Log messages do not include buffer usage or congestion information. To view this information, use the [show queue-monitor length global-buffer](#) command.

The `no queue-monitor length global-buffer log` and `default queue-monitor length global-buffer log` commands disable global buffer logging by removing the corresponding `queue-monitor length global-buffer log` command from **running-config**. The `queue-monitor length global-buffer log` command with an interval value of **0** also disables global buffer logging.

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor length global-buffer log interval
no queue-monitor length global-buffer log
default queue-monitor length global-buffer log
```

##### Parameters

**interval** minimum interval in seconds between logged messages.

- **0** global buffer logging is disabled on the switch (the default setting).
- **1** to **65535** minimum logging interval (in seconds).

##### Guidelines

This command is available on FM6000 platform switches.

##### Examples

- This command enables global buffer logging with a minimum interval of **10** seconds between messages.

```
switch(config)# queue-monitor length global-buffer log 10
```

- This command disables global buffer logging on the switch.

```
switch(config)# no queue-monitor length global-buffer log
```

#### 21.2.4.7 queue-monitor length global-buffer thresholds

The `queue-monitor length global-buffer thresholds` command sets global buffer thresholds for the switch. An over-threshold event is generated when usage of the global buffer exceeds the upper threshold, and over-threshold events continue to be generated until usage drops below the lower threshold. (To log these events, use the [queue-monitor length global-buffer log](#) command.)

The `no queue-monitor length global-buffer` and `default queue-monitor length global-buffer` commands disable global buffer reporting.

The `no queue-monitor length global-buffer thresholds` and `default queue-monitor length global-buffer thresholds` commands erase custom global buffer threshold settings.

---

## Command Mode

Global Configuration

### Command Syntax

```
queue-monitor length global-buffer thresholds max_segments min_segments
no queue-monitor length global-buffer log
default queue-monitor length global-buffer log
```

### Parameters

- **max\_segments** upper threshold in 160-byte segments. Value ranges from **2** to **36864**. Default is **10940**.
- **min\_segments** lower threshold in 160-byte segments. Value ranges from **1** to **36864**. Default is **4376**.

### Examples

- This command sets the upper and lower global buffer thresholds to **9000** segments and **3000** segments.

```
switch(config)# queue-monitor length global-buffer thresholds 9000 3000
switch(config)#

```

- This command resets the upper and lower global buffer thresholds to their default values.

```
switch(config)# no queue-monitor length global-buffer thresholds 9000 3000
switch(config)#

```

#### 21.2.4.8 queue-monitor length global-buffer

The `queue-monitor length global-buffer` command includes global buffer usage in LANZ reporting.

When global buffer reporting is enabled, over-threshold events are generated when global buffer usage exceeds the upper threshold. To set the threshold value, use the `queue-monitor length global-buffer thresholds` command. Usage data may be viewed using the `show queue-monitor length global-buffer` command. To view status and threshold information, use the `show queue-monitor length status` command.

Global buffer usage is measured in segments of **160** bytes.

The `no queue-monitor length global-buffer` and `default queue-monitor length global-buffer` commands disable global buffer usage reporting by removing the corresponding `queue-monitor length global-buffer` command from *running-config*.

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor length global-buffer
no queue-monitor length global-buffer
default queue-monitor length global-buffer
```

##### Guidelines

This command is available on FM6000 platform switches.

##### Examples

- This command enables global buffer monitoring on the switch.

```
switch(config)# queue-monitor length global-buffer
switch(config) #
```

- This command disables global buffer monitoring on the switch.

```
switch(config)# no queue-monitor length global-buffer
switch(config) #
```

---

#### 21.2.4.9 queue-monitor length log

The `queue-monitor length log` command enables logging of queue-length over-threshold events when LANZ is enabled on the switch (see [queue-monitor length \(global configuration mode\)](#)). When logging is enabled, a log message is generated each time one or more queues on an interface exceed the upper threshold value for that interface (see [queue-monitor length threshold \(Arad/Jericho/Qumran\)](#)). Once an interface is over threshold, additional messages are generated at a maximum rate of one per interval as long as the queue length remains above the lower threshold for that interface. No syslog message is generated when queue length drops back under threshold.

Logging is disabled by default.

Log messages do not include queue length information. To view queue length information, use the [show queue-monitor length](#) command.

The queue-monitor length log command with an interval value of 0 disables event logging.

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor length log interval
```

##### Parameters

**interval** minimum interval in seconds between logged messages from a single interface.

- **0** queue-length logging is disabled on the switch (the default setting).
- **1 to 65535** minimum logging interval (in seconds).

##### Examples

- This command enables over-threshold logging with a minimum interval of **10** seconds between messages for a given interface.

```
switch(config)# queue-monitor length log 10
```

- This command disables queue-length over-threshold logging on the switch.

```
switch(config)# queue-monitor length log 0
```

- This is an example of a queue-length log message.

```
Oct 27 12:48:22 switch QUEUE_MONITOR-6-LENGTH OVER_THRESHOLD: Interface
Ethernet6 queue length is over threshold of 512, current length is 1024.
```

#### 21.2.4.10 queue-monitor length mirror

The `queue-monitor length mirror` command enables LANZ mirroring. As a result, the switch is configured to automatically send congested traffic to either the CPU or an Ethernet egress interface destination, once a queue threshold is crossed. To set the destination for the mirrored traffic, use the [queue-monitor length mirror destination](#) command.

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor length mirror
```

##### Examples

- This command enables LANZ traffic sampling.

```
switch(config)# queue-monitor length mirror
switch(config)#
```

- This command disables LANZ traffic sampling.

```
switch(config)# no queue-monitor length mirror
switch(config)#
```

---

#### 21.2.4.11 queue-monitor length mirror destination

The `queue-monitor length mirror destination` command results in automatically sending traffic experiencing congestion to either the CPU or an Ethernet egress interface destination, once a queue threshold is crossed. Before using this command, first enable LANZ mirroring through the command [queue-monitor length mirror](#).

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor length mirror destination cpu | ports
```

##### Parameter

*ports* any combination of Ethernet ports **1** through **24**.

##### Examples

- This command configures LANZ traffic sampling for a CPU interface mirror destination.

```
switch(config)# queue-monitor length mirror destination cpu
switch(config) #
```

- This command configures LANZ traffic sampling for an Ethernet interface mirror destination for ports **3**, **11**, and **15** through **20**.

```
switch(config)# queue-monitor length mirror destination Ethernet 3,11,15-20
switch(config) #
```

### 21.2.4.12 queue-monitor length notifying

The `queue-monitor length notifying` command enables Notifying Mode on Arad and Jericho switches. By default, LANZ operates in Polling Mode on Arad and Jericho switches. On all other switches, LANZ operates only in Notifying Mode.

When Notifying Mode is enabled, the switch provides detailed congestion information including Start, Update, and End events, rather than only polling the most congested queue in each ASIC. Notifying Mode uses both upper and lower threshold values. Both can be set with the `queue-monitor length thresholds` command. While a queue is congested, the maximum queue size is updated every five seconds by default; this interval can be configured using the `queue-monitor length update-interval` command.

The `no queue-monitor length notifying` and `default queue-monitor length notifying` commands reset LANZ to the default Polling Mode.

#### Command Mode

Global Configuration

#### Command Syntax

```
queue-monitor length notifying
no queue-monitor length notifying
default queue-monitor length notifying
```

#### Guidelines

- Polling mode is available only on Arad and Jericho platform switches.
- On Jericho platforms, LANZ will revert to Polling Mode if there are not enough counter resources to operate in Notifying Mode.
- On Arad platforms, Notifying Mode is incompatible with SSO. Enabling SSO while Notifying Mode is enabled will cause LANZ to revert to Polling Mode.
- On Arad platforms, Notifying Mode is not available for CPU queues. Use Polling Mode when monitoring congestion on CPU queues on Arad switches.
- If the switch is rebooted while Notifying Mode is enabled, queue threshold values may be lost.

#### Examples

- This command enables Notifying Mode on an Arad or Jericho switch.

```
switch(config) # queue-monitor length notifying
switch(config) #
```

- This command disables Notifying Mode on an Arad or Jericho switch, returning LANZ to the default Polling Mode.

```
switch(config) # no queue-monitor length notifying
switch(config) #
```

### 21.2.4.13 queue-monitor length thresholds

The `queue-monitor length thresholds` command sets both upper and lower queue length thresholds to define “congested” on the command-mode interface for purposes of LANZ reporting. If LANZ is enabled (see [queue-monitor length \(global configuration mode\)](#)), an over-threshold event is generated when one or more queues on the interface exceed the upper threshold, and over-threshold events continue to be generated until all queue lengths on the interface drop below the lower threshold. (To log these events, use the `queue-monitor length log` command.)

---

Entering the `no queue-monitor length` command in interface configuration mode disables LANZ on the interface. Entering either the `queue-monitor length` command or the `default queue-monitor length` command in interface configuration mode enables LANZ on the interface by removing the `no queue-monitor length` command from the configuration.

The `no queue-monitor length thresholds` and `default queue-monitor length thresholds` commands in interface configuration mode both erase custom queue length threshold settings for the interface.

## Command Mode

Interface-Ethernet Configuration

### Command Syntax

```
queue-monitor length thresholds upper_limit lower_limit
```

```
no queue-monitor length
```

```
default queue-monitor length
```

### Parameters

- ***upper\_limit*** queue length in segments that triggers an over-threshold event. Must be higher than ***lower\_limit***. The minimum value is 2. The maximum is the largest number of segments which can be queued before packets are dropped, and varies based on factors including flow control state and private buffer settings. Default setting is **512**.
- ***lower\_limit*** lower queue length threshold in segments. When logging is enabled, an over-threshold interface continues generating over-threshold events until all its queues drop back below this length. Must be lower than ***upper\_limit***. Values range from **1** to **4806**. Default setting is **256**.

### Guidelines

Queue lengths are measured in 480-byte segments on FM6000 switches, in 208-byte segments on Trident II and Tomahawk switches, in 256-byte segments on Trident 3 switches, and in bytes on Arad and Jericho switches. Default thresholds vary by platform. Both upper and lower thresholds are configurable.

### Examples

- These commands set the upper and lower queue-length thresholds on **interface ethernet 5** to **300** segments and **200** segments.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# queue-monitor length thresholds 300 200
switch(config-if-Et5) #
```

- These commands reset the upper and lower queue-length thresholds on **interface ethernet 5** to their default values.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# default queue-monitor length thresholds
switch(config-if-Et5) #
```

#### 21.2.4.14 queue-monitor length threshold (Arad/Jericho/Qumran)

The `queue-monitor length threshold` command sets the upper queue-length threshold on Arad, Jericho, and Qumran platforms to define “congested” on the command-mode interface for purposes of LANZ reporting. If LANZ is enabled (see [queue-monitor length \(global configuration mode\)](#)), an over-threshold event is generated when one or more queues on the interface exceed the upper threshold, and over-threshold events continue to be generated until all queue lengths on the interface drop below the lower threshold. (To log these events, use the `queue-monitor length log` command.)

Entering the `no queue-monitor length` command in interface configuration mode disables LANZ on the interface. Entering either the `queue-monitor length threshold` command or the `default queue-monitor length threshold` command enables LANZ on the interface by removing the `no queue-monitor length` command from the configuration.

The `no queue-monitor length threshold` and `default queue-monitor length threshold` commands erase custom queue length threshold settings for the interface.

#### Command Mode

Interface-Ethernet Configuration

#### Command Syntax

```
queue-monitor length threshold upper_limit
no queue-monitor length
default queue-monitor length
```

#### Parameters

*upper\_limit* is the queue length in bytes that triggers an over-threshold event. Values range from **40962** to **52428800** bytes. Default setting is **52428800**.

#### Guidelines

On Arad, Jericho, and Qumran platforms, the queue length is measured in bytes. Only the upper threshold is configurable using this command, and it is set at a default value of **52428800** bytes. Both upper and lower thresholds can be set using the [queue-monitor length thresholds](#) command.

#### Examples

- These commands set the upper queue-length threshold on `interface ethernet 3/30` to **40000000** bytes.

```
switch(config)# interface ethernet 3/30
switch(config-if-Et3/30)# queue-monitor length threshold 40000000
switch(config-if-Et3/30)#[/pre]
```

- These commands reset the upper queue-length threshold on `interface ethernet 3/30` to its default value of **52428800** bytes.

```
switch(config)# interface ethernet 3/30
switch(config-if-Et3/30)# default queue-monitor length threshold
switch(config-if-Et3/30)#[/pre]
```

---

#### 21.2.4.15 queue-monitor length update-interval

The `queue-monitor length update-interval` command sets the interval between congestion updates when LANZ is in Notifying Mode.

The `no queue-monitor length update-interval` and `default queue-monitor length update-interval` commands reset the update interval to its default value of **5000000** (**5** seconds).

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor length update-interval interval
no queue-monitor length
default queue-monitor length
```

##### Parameter

**interval** is the time in microseconds between congestion updates. Values range from **80-10000000**; default setting is **5000000** (**5** seconds).

##### Examples

- This command sets the time between congestion updates to **10** seconds.

```
switch(config)# queue-monitor length update-interval 10000000
switch(config)#{}
```

- This command resets the time between congestion updates to its default value of **5** seconds.

```
switch(config)# default queue-monitor length update-interval
switch(config)#{}
```

#### 21.2.4.16 queue-monitor streaming

The **queue-monitor streaming** command places the switch in queue-monitor-streaming configuration mode. Queue-monitor-streaming configuration mode is not a group change mode; **running-config** is changed immediately upon command entry. The **exit** command does not affect **running-config**.

To enable LANZ data streaming on the switch, use the **no show queue-monitor streaming clients** command.

The **exit** command returns the switch to global configuration mode.

##### Command Mode

Global Configuration

##### Command Syntax

```
queue-monitor streaming
```

##### Commands Available in queue-monitor streaming Configuration Mode

- [max-connections](#)
- [show queue-monitor streaming clients](#)

##### Example

This command places the switch in the **queue-monitor streaming** configuration mode.

```
switch(config) # queue-monitor streaming
switch(config-qm-streaming) #
```

### 21.2.4.17 show queue-monitor length

The **show queue-monitor length** command displays a report of recent over-threshold events for all interfaces, limited to the last **1000** records, with the newest events listed first.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

To limit the output to a specified number of seconds and/or records, use the [show queue-monitor length limit](#) command.

#### Command Mode

EXEC

#### Command Syntax

```
show queue-monitor length
```

#### Examples

- This command displays the last **1000** LANZ records on an Arad or Jericho platform switch in Polling Mode.

```
switch> show queue-monitor length

---

#### 21.2.4.18 show queue-monitor length all

The **show queue-monitor length all** command displays all available over-threshold event records on the switch including global buffer information, with the most recent events listed first.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

#### Command Mode

EXEC

#### Command Syntax

```
show queue-monitor length all
```

#### Guidelines

This command is available on FM6000 platform switches.

#### Example

This command displays all available LANZ records from the switch.

```
switch> show queue-monitor length all

Report generated at 2013-04-01 13:23:13
E-End, U-Update, S-Start, TC-Traffic Class
GH-High, GU-Update, GL-Low
Segment size for E, U and S congestion records is 480 bytes
Segment size for GL, GU and GH congestion records is 160 bytes
* Max queue length during period of congestion
+ Period of congestion exceeded counter

```

### 21.2.4.19 show queue-monitor length cpu

The **show queue-monitor length cpu** command displays LANZ data for CPU ports on the switch. On Trident II and Tomahawk platforms, the “Interface” column identifies the CPU port by its card slot and chip index.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

#### Command Mode

EXEC

#### Command Syntax

```
show queue-monitor length cpu
```

#### Examples

- This command displays LANZ data for CPU ports on a Trident II or Tomahawk switch.

| Type | Time              | Interface<br>(TC) | Congestion<br>duration<br>(usecs) | Queue<br>length<br>(segments) | Time of Max<br>Queue length<br>relative to<br>congestion<br>start<br>(usecs) | Fabric<br>Peer |

#### 21.2.4.20 show queue-monitor length csv

The **show queue-monitor length csv** command displays LANZ records in Comma-Separated Value (CSV) format with the oldest samples displayed first.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

##### Command Mode

EXEC

##### Command Syntax

```
show queue-monitor length csv
```

##### Example

This command displays LANZ records in CSV format.

```
switch> show queue-monitor length csv

```

### 21.2.4.21 show queue-monitor length drops

The **show queue-monitor length drops** command displays a report of cumulative transmission drop totals for a range of interfaces or for all interfaces. Output can be limited to a specified number of seconds or records. The most recent events are listed first. By default, the command displays data for all interfaces, limited to the last 1000 records. Newest events are listed first.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

#### Command Mode

EXEC

#### Command Syntax

```
show queue-monitor length [INTERFACES][FACTOR] drops
```

#### Parameters

- **INTERFACES** interface type and number for report. Values include:
  - **no parameter** displays information for all interfaces.
  - **ethernet e-range** e-range formats include a number, number range, or comma-delimited list of numbers and ranges.
- **FACTOR** limiting parameter for report. Values include:
  - **no parameter** displays the last **1000** records.
  - **limit number samples** displays the last **number** records.
  - **limit number seconds** displays all records generated during the last **number** seconds. Value of number ranges from **1** to **1000000**.

#### Guidelines

This command is available on FM6000, Trident II, Trident 3, and Tomahawk platform switches.

#### Examples

- This command displays the last **10** records of transmission drop data on an FM6000 switch.

```
switch> show queue-monitor length limit 10 samples drops

## 21.2.4.22 show queue-monitor length ethernet

The **show queue-monitor length ethernet** command displays a report of recent over-threshold events for a range of interfaces, with the newest events listed first.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

### Command Mode

EXEC

### Command Syntax

```
show queue-monitor length ethernet e-range
```

### Parameters

**e-range** the range of interfaces to be included in the report; formats include a number, number range, or comma-delimited list of numbers and ranges

### Examples

- This command displays the last **1000** records for **interface ethernet 9** on an FM6000 platform switch.

```
switch> show queue-monitor length ethernet 9

---

#### 21.2.4.23 show queue-monitor length global-buffer

The **show queue-monitor length global-buffer** command displays a report of recent high usage, low usage and update events for the global buffer. Newest events are listed first.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

##### Command Mode

EXEC

##### Command Syntax

```
show queue-monitor length global-buffer
```

##### Guidelines

This command is available on FM6000 platform switches.

##### Example

This command displays the global buffer event records for the switch.

```
switch> show queue-monitor length global buffer
Report generated at 2013-04-01 14:30:07

#### 21.2.4.24 show queue-monitor length limit

The `show queue-monitor length limit` command displays a report of recent over-threshold events for a range of interfaces or for all interfaces, limited by a specified number of records.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

##### Command Mode

EXEC

##### Command Syntax

```
show queue-monitor length limit [[INTERFACES]] number
```

##### Parameters

- **INTERFACES** interface type and number for report. Values include:
  - ***no parameter*** displays information for all interfaces.
  - **ethernet e-range** e-range formats include a number, number range, or comma-delimited list of numbers and ranges.
- ***number*** number of records to display. Values range from **1** to **1000000**.

##### Example

This command displays the last **100** records for interface ethernet **6** through **8**.

```
switch># show queue-monitor length ethernet 6-8 limit 100 samples
Report generated at 2010-01-01 12:56:13

#### **21.2.4.25 show queue-monitor length statistics**

The **show queue-monitor length statistics** command displays LANZ statistics for all interfaces, showing the traffic class and number of recorded congestion events for each interface.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

##### **Command Mode**

EXEC

##### **Command Syntax**

```
show queue-monitor length statistics
```

##### **Example**

This command displays LANZ statistics for all interfaces on the switch.

```
switch> show queue-monitor length statistics
Report generated at 2016-02-09 22:59:56
Interface Traffic Class Count

Et29 11 1
```

### 21.2.4.26 show queue-monitor length status

The **show queue-monitor length status** command displays the current LANZ configuration for the switch and for each interface. On certain platforms, the status of global buffer monitoring and per-linecard LANZ mode are displayed.

#### Command Mode

EXEC Global Configuration

#### Command Syntax

```
show queue-monitor length status
```

#### Guidelines

On FM6000 platform switches, this command includes status information about global buffer monitoring.

On Arad and Jericho based linecards, if LANZ is globally enabled (using the [queue-monitor length \(global configuration mode\)](#) command), the command displays the monitoring mode per-linecard.

On Arad and Jericho switches, even when all linecards are configured in Notifying Mode (using the [queue-monitor length notifying](#) command), some linecards may still run LANZ in Polling Mode under the following circumstances:

- On Arad-based linecards, LANZ falls back to Polling Mode when SSO redundancy mode is configured on the card (here, the mode is shown as “polling due to SSO configured”).
- On Jericho-based linecards, LANZ may run in Polling Mode when many features that use the switch’s statistic capabilities have been configured (here, the mode is shown as “polling due to counters exhausted”).

#### Examples

- This command displays the current LANZ configuration on an FM6000 device.

```
switch# show queue-monitor length status
queue-monitor length enabled
queue-monitor length packet sampling is disabled
queue-monitor length update interval in micro seconds: 5000000
Global Buffer Monitoring

Global buffer monitoring is enabled
Segment size in bytes : 160
Total buffers in segments : 49152
High threshold : 16862
Low threshold : 6745

Per-Interface Queue Length Monitoring

Queue length monitoring is enabled
Segment size in bytes : 480
Maximum queue length in segments : 5621
Port thresholds in segments:
Port High threshold Low threshold Mirroring Enabled
Cpu 512 256 True
Et1 512 256 True
Et2 512 256 True
Et3 512 256 True
Et4 512 256 True
Et5 512 256 True
Et6 512 256 True
Et7 512 256 True
 True switch#
```

- This command displays the current LANZ configuration on a Trident II or Tomahawk device.

```
switch# show queue-monitor length status
```

```

queue-monitor length enabled
queue-monitor length packet sampling is disabled
queue-monitor length update interval in micro seconds: 5000000
Per-Interface Queue Length Monitoring

Queue length monitoring is enabled
Segment size in bytes : 208
Maximum queue length in segments : 16382
Port thresholds in segments:
Port High threshold Low threshold
Cpu 512 256
Et1/1 512 256
Et1/2 512 256
Et1/3 512 256
Et1/4 512 256
Et2/1 512 256
Et2/2 512 256
Et2/3 512 256 switch#

```

- This command displays the current LANZ configuration on an Arad or Jericho device.

```

switch# show queue-monitor length status
queue-monitor length enabled
queue-monitor length packet sampling is disabled
queue-monitor length update interval in micro seconds: 5000000
Per-Interface Queue Length Monitoring

Queue length monitoring is enabled
Queue length monitoring mode is notifying
Queue length monitoring status is:
Linecard3 polling due to SSO configured
Linecard4 polling due to SSO configured
Linecard5 polling due to SSO configured
Linecard6 polling due to SSO configured
Maximum queue length in bytes : 524288000
Port thresholds in bytes:
Port High threshold Low threshold Warnings
Cpu 65536 32768
Et3/1/1 5242880 2621440
Et3/1/2 5242880 2621440

Et3/1/7 5242880 2621440
Et3/1/8 5242880 2621440

```

### 21.2.4.27 show queue-monitor length tx-latency

The **show queue-monitor length tx-latency** command displays the latency data of recent LANZ events for a range of interfaces or for all interfaces. Output can be limited to a specified number of seconds or records. The most recent events are listed first. By default, the command displays data for all interfaces, limited to the last 1000 records. Newest events are listed first.

LANZ must be enabled to use this command (see [queue-monitor length \(global configuration mode\)](#)). If LANZ is disabled, the command displays “queue-monitor is disabled.”

#### Command Mode

EXEC

#### Command Syntax

```
show queue-monitor length [[INTERFACES][FACTOR]] tx-latency
```

#### Parameters

- **INTERFACES** interface type and number for report. Values include:
  - **no parameter** displays information for all interfaces.
  - **ethernet e-range** e-range formats include a number, number range, or comma-delimited list of numbers and ranges.
- **FACTOR** limiting parameter for report. Values include:
  - **no parameter** displays the last **1000** records.
  - **limit number samples** displays the last **number** records.
  - **limit number seconds** displays all records generated during the last **number** seconds. Value of number ranges from **1** to **1000000**.

#### Guidelines

This command is available on FM6000, Trident II, Trident 3, and Tomahawk platform switches.

#### Example

This command displays transmission latency data for the last **1000** LANZ events on the switch.

```
switch> show queue-monitor length tx-latency
Report generated at 2017-03-10 15:40:02
Time Interface(TC) Tx-Latency (usecs)

0:02:29.99222 ago Et23/3(1) 724.868
0:02:32.33178 ago Et23/3(1) 724.684
0:02:37.33134 ago Et23/3(1) 724.684
0:02:42.33135 ago Et23/3(1) 724.684
0:02:47.33135 ago Et23/3(1) 724.684
0:02:52.33106 ago Et23/3(1) 730.985
switch>
```

---

#### **21.2.4.28 show queue-monitor streaming clients**

The **show queue-monitor streaming clients** command displays the number of presently connected clients through LANZ streaming, and also displays their host-names. Ensure that both LANZ and LANZ streaming are enabled in order to use this command.

##### **Command Mode**

EXEC

##### **Command Syntax**

```
show queue-monitor streaming clients
```

##### **Example**

This command displays the number of clients connected to LANZ streaming.

```
switch# show queue-monitor streaming clients
Number of clients connected: 3

172.20.63.161:6565
172.24.17.58:42
172.38.54.142:333
```

#### 21.2.4.29 shutdown (queue-monitor-streaming configuration)

The **shutdown** command disables the streaming of LANZ data to external clients. The **no shutdown** command enables LANZ data streaming. Streaming is disabled by default.

##### Command Mode

Queue-Monitor-Streaming Configuration

##### Command Syntax

```
shutdown
```

```
no shutdown
```

##### Example

These commands enable the streaming of LANZ data on the switch.

```
switch(config) # queue-monitor streaming
switch(config-qm-streaming) # no shutdown
switch(config-qm-streaming) #
```

---

#### 21.2.4.30 tcpdump queue-monitor

The **tcpdump queue-monitor** command exports congested traffic to a packet capture device or another tool for analysis, or directly to the switch CPU for inspection.

##### Command Mode

Global Configuration

##### Command Syntax

```
tcpdump queue-monitor [file | filecount | filter | lookup-names | max-file-size | packet-count | size | verbose]
```

##### Parameters

- **file** output file.
  - **certificate:** certificate file.
    - **file:** standard file.
    - **flash:** flash file.
    - **sslkey:** sslkey file.
    - **usb1:** usb1 file.
- **filecount** specify the number of output files: **1 to 100**.
- **filter** set the filtering expression to select which packets will be dumped.
- **lookup-names** enable reverse DNS lookups.
- **max-file-size** specify the maximum file size by entering **1 to 100** million bytes.
- **packet-count** specify **1 to 10000** packets to capture.
- **size** specify the maximum number of bytes to dump per packet with a size of **1 to 65536** bytes.
- **verbose** enable verbose mode.

##### Example

This command inspects traffic on the switch.

```
switch(config)# tcpdump queue-monitor
tcpdump: WARNING: lanz: no IPv4 address assigned
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on lanz, link-type EN10MB (Ethernet), capture size 65535 bytes
...
0 packets captured
0 packets received by filter
0 packets dropped by kernel
switch(config) #
```

## 21.3 Sampled Flow Tracking

This chapter describes Arista's implementation of sampled flow tracking, including configuration instructions and command descriptions. Topics covered by this chapter include:

- [Sampled Flow Tracking Overview](#)
- [Configuring Sampled Flow Tracking](#)
- [Hardware Flow Tracking with IPFIX Export](#)
- [Postcard Telemetry](#)
- [Inband Network Telemetry \(INT\) Support](#)
- [Sampled Flow Tracking Configuration Examples](#)
- [Sampled Flow Tracking Commands](#)

### 21.3.1 Sampled Flow Tracking Overview

Network administrators require access to traffic flow information that passes through various network elements to analyze and monitor networks. Sampled Flow Tracking provides access to IP flow information by sampling traffic flows in the ingress direction on the configured interfaces. The samples create flow records exported to the configured collectors in the Internet Protocol Flow Information Export (IPFIX) format.

#### Sampled Flow Tracking Terminology

- **Flow tracker** - A collection of interfaces that collects samples and creates flow records. The flow tracker has one or more exporters.
- **Exporter** - Sends flow records to one or more collectors.
- **Collector** - Receives flow records from one or more exporters.
- **Data record** - Contains values of the parameters corresponding to a template record.
- **Template record** - Defines the structure and interpretation of fields in a data record with an ordered sequence of type and length pairs.
- **Options template record** - Defines a template record with the structure and interpretation of fields in a data record, including scoping the applicability of the data record.

Sampled Flow Tracking creates data records based on the following flow key fields:

- Source IP address
- Destination IP address
- IP protocol
- Source port
- Destination port
- VRF
- VLAN

These records support IPv4 and IPv6 flow data records.

Sampled Flow Tracking supports the following optional data records:

- **VRF record** - Mapping of the VRF ID to the VRF name.
- **Interface record** - Mapping of the interface ID to the interface name.
- **Flow key indicator record** - Mapping of template ID to flow key indicator.
- **Flow tracker record** - Information about configured flow tracker.

---

Sampled Flow Tracking supports selective sampling of certain traffic types, specified globally, such as routed IPv4, routed IPv6, MPLS pop, and route IPv4 per interface.

The following interfaces support this feature:

- Interfaces
- Subinterfaces
- Port Channels
- Port Channel Subinterfaces

#### 21.3.1.1 Sampled Flow Tracking Limitations

The limitations of Sampled flow tracking are:

- Sampled flow tracking is active only when sFlow is disabled on the device.
- Sampled flow tracking does not support export of IPFIX messages over ECMP paths.
- Sampled flow tracking route simulation is not supported for ECMP paths.

#### 21.3.2 Configuring Sampled Flow Tracking

##### Configuring Sampled Flow Tracking

Use the **flow tracker sampled** command to enable sampled flow tracking on a tracker. Each tracker should have a minimum of one exporter configured.

##### Example

This command enables sampled flow tracking on an interface **Eth1** and the flow tracker **ftr1**.

```
switch(config)# interface Eth1
switch(config-if-Eth1)# flow tracker sampled ftr1
```

Use the **sample** command to enable the sample rate for a specific sampled flow tracker. The default sample rate is **1048576**.

##### Example

These commands configure a sample rate of **1024** for the sampled flow tracker.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# sample 1024
```

#### 21.3.2.1 Configuring the Sampled Flow Tracker

Use the **tracker** command to configure a sampled flow tracker for a device.

##### Example

This command configures a sampled flow tracker named **ftr1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
```

Use the **record export on interval** command to configure the interval to export active flow records. The default interval is **300000** milliseconds.

### Example

These commands configure an active record interval of **7000** for the exporter **exp1**.

```
switch(config) # flow tracking sampled
switch(config-flow-tracking-sampled) # tracker ftr1
switch(config-ftr-sampled-tr-ftr1) # exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1) # record export on interval 7000
```

Use the **record export on inactive timeout** command to configure the interval to export timed-out inactive flow records. The default interval is **15000** milliseconds.

These commands configure an inactive record interval of **4000** for the exporter **exp1**.

```
switch(config) # flow tracking sampled
switch(config-flow-tracking-sampled) # tracker ftr1
switch(config-ftr-sampled-tr-ftr1) # exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1) # record export on inactive timeout 4000
```

#### 21.3.2.2 Configuring an Exporter for Sampled Flow Tracker

Use the **exporter** command to configure or unconfigure an exporter for a specific tracker.

### Example

This command configures exporter **exp1** for the specific tracker **ftr1**.

```
switch(config) # flow tracking sampled
switch(config-flow-tracking-sampled) # tracker ftr1
switch(config-ftr-sampled-tr-ftr1) # exporter exp1
```

Use the **collector** command to configure the collector for the specific exporter.

### Example

These commands configure a collector for the IPv4 address **192.0.2.0** and collector port number **10**.

```
switch(config) # flow tracking sampled
switch(config-flow-tracking-sampled) # tracker ftr1
switch(config-ftr-sampled-tr-ftr1) # exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1) # collector 192.0.2.0 port 10
```

Use the **local interface** command to configure the local source interface for the specific exporter.

### Example

These commands configure the local source **interface Ethernet1** for the exporter **exp1**.

```
switch(config) # flow tracking sampled
switch(config-flow-tracking-sampled) # tracker ftr1
switch(config-ftr-sampled-tr-ftr1) # exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1) # local interface Ethernet1
```

Use the **dscp** command to configure the DSCP value for the specific exporter. The default DSCP value is **0**.

### Example

---

These commands configure a DSCP value of **10** for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# dscp 10
```

Use the **format ipfix version** command to configure the IPFIX version and maximum packet size for the specific exporter. The default IPFIX version is **10** and the default maximum packet size is **9152**.

### Example

These commands configure an IPFIX version of **10** and a maximum packet size of **854** for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# format ipfix version 10 max-packet-size 854
```

Use the **template interval** command to configure the interval to export templates for the specific exporter. The default template interval is **3600000** milliseconds.

### Example

This command configures the interval of **3400000** milliseconds for the exporter **exp1**.

```
switch(config-ftr-sampled-tr-exp-ftr1-exp1)# template interval 3400000
```

## 21.3.3 Hardware Flow Tracking with IPFIX Export

Hardware Flow Tracking uses match criteria to collect data from packets based on defined flow profiles. EOS sends the collected data to an external node called a Collector using the IPFIX flow export protocol. The flow tracking engine tracks up to 32K flows going through a given set of ports on a switch with IPFIX-capability. Configure Flow Tracking on physical interfaces or LAG interfaces. EOS supports the following matching fields in the packet header:

- IP Source
- IP Destination
- IP Protocol
- IP Protocol Source Port
- IP Protocol Destination Port

The switch collects the following information:

- Byte Count (4 bytes)
- Packet Count (4 bytes)
- New-learn Timestamp
- Flow Start Timestamp
- Flow End Timestamp

### Configuring Hardware Flow Tracking

This file extract displays a Hardware Flow Tracking configuration.

```
! Define a loopback interface to act as the local source interface for
! IPFIX export
int Loopback0
```

```

ip address 1.2.3.4/32

@ Enable IP routing for IPFIX packet to be routed to the collector
ip routing

! The flow tracker definition
flow tracking hardware
 tracker myFtr
 record export on inactive timeout 60000
 record export on interval 30000
 !
 exporter myExporter
 local interface Loopback0
 template interval 5000
 collector 172.28.130.153
 no shutdown

! Flow tracked interface/port
int Ethernet48
 flow tracker hardware myFtr
 no shutdown

```

This command displays general information about Hardware Flow Tracking.

```

switch# show flow tracking hardware
Flow Tracking Status
 Type: Hardware
 Running: yes
 Tracker: myFtr
 Active interval: 30000ms
 Inactive timeout: 60000ms

| 266                                                  | 0x3e8              |

### 21.3.4 Postcard Telemetry

The Postcard Telemetry feature gathers per flow telemetry information such as data paths and per hop latency. The path, latency, and congestion information for flows at different times assist with troubleshooting and monitoring flows. Postcard Telemetry samples flows at every switch, aggregates them, and sends the samples to a collector with path and latency information using GRE encapsulation. For calculating latency information, switches in the network need to be synchronized using the PTP protocol.

Postcard Telemetry collects the following information:

- Length of the truncated samples in bytes
- 48-bit timestamp
- SNMP OID values of Ingress and Egress ports
- 16-bit IP payload checksum that uniquely identifies the sample of the same packet from different switches at the collector.
- Sample Rate with a multiplier of 1K
- Sample data, packet inclusive of L2 header, truncated to 256 bytes

#### Configuration Considerations

EOS supports the following features for Postcard Telemetry:

- An IPv4 collector on default VRF only
- IPv4 match rules in a sample policy only
- Sampling packets with matching TCP control flags
- IPv4 PBR forwarded packets for sampling
- Postcard Telemetry for DirectFlow forwarded packets

EOS does not support the following features:

- VXLAN-encapsulated packets
- Packets with IP options
- Multi-destination packets
- Packets dropped or consumed by switch
- DCS-7280 and DCS-7500 platforms supports up to three (3) postcard policies

#### 21.3.4.1 Configuring a TCAM Profile for Postcard Telemetry

The Postcard Telemetry feature requires a user-defined TCAM profile to enable Postcard Telemetry.

The system TCAM profile must support the **telemetry postcard policy ipv4** to support postcard telemetry for IPv4 packets for IPv4 packets in copied or newly created TCAM profiles.

##### Creating the User-defined TCAM Profile

Use the following command to add Postcard Telemetry to the default profile.

```
switch(config)# hardware tcam
switch(config-hw-tcam)# profile <profile name> copy default
switch(config-hw-tcam-profile-<profile>)# feature telemetry postcard policy ipv4 copy
switch(system-feature-source-profile)#+
```

Enable Postcard Telemetry for IPv4 bridged and routed packets.

```
switch(config-hw-tcam-profile-<profile>-feature-<feature>)# packet ipv4 forwarding bridged
switch(config-hw-tcam-profile-<profile>-feature-<feature>)# packet ipv4 forwarding routed
```

Optionally, configure the key size limit as 160.

```
switch(config-hw-tcam-profile-<profile>-feature-<feature>)# key size limit 160
```

Remove the unused features to ensure Postcard Telemetry allocation on the TCAM DB.

```
switch(config-hw-tcam-profile-<profile>-feature-<feature>)# exit
switch(config-hw-tcam-profile-<profile>)# no feature mirror ip
switch(config-hw-tcam-profile-<profile>)#+
```

##### Applying the User-defined TCAM Profile

Use the following command to set the system profile under the **hardware tcam** mode.

```
switch(config-hw-tcam)# system profile <profilename>
```

When the system TCAM profile changes, some agents restart on the switch. This removes the unused features to ensure Postcard Telemetry allocation on the TCAM DB.

#### 21.3.5 Inband Network Telemetry (INT) Support

The Inband Network Telemetry, eXport Data (INT-XD) gathers flow, queue, and drop telemetry information such as network path, hop latency, queue congestion, and drop reasons used for network monitoring and troubleshooting.

The INT-XD supports the following features:

- Flow telemetry report generates from flow events. Flow events include new flows, change in the attributes of flow such as ingress/egress port or latency. Flow reports include information about the path that packets traverse as well as other telemetry metadata such as hop latency and queue occupancy.
- Drop reports provide visibility into the impact of packet drops on user traffic. Drop reports include information about the path that packets traversed as well as other telemetry metadata such as drop reason code and queue ID.

- 
- Queue congestion reports generate from queue-related events, such as packets exceeding the queue depth or latency. This provides visibility into the traffic causing and prolonging queue congestion.

## Platform Compatibility

The following platforms support the INT-XD feature.

- DCS-7170-64C-F
- DCS-7170-64C-R
- DCS-7170-64C#
- DCS-7170-64C-M#
- DCS-7170-32C-F
- DCS-7170-32C-R
- DCS-7170-32C#
- DCS-7170-32C-M-F
- DCS-7170-32C-M-R
- DCS-7170-32C-M#
- DCS-7170-32CD-F
- DCS-7170-32CD-R
- DCS-7170-32CD#

## Configuration

All switches have same configuration for INT-XD and postcard telemetry to give correct information to collector and supported only in the default profile.

```
switch(config)# platform barefoot profile default
```

This command enters the postcard telemetry context to enable the feature.

```
switch(config)# monitor telemetry postcard int-xd
```

This command enables the postcard telemetry.

```
switch(config-tele-postcard-int-xd)# no disabled
```

Enable flow report.

```
switch(config-tele-postcard-int-xd)# report flow
```

Configure the flow report refresh interval. By default, EOS uses 5 seconds.

```
switch(config-tele-postcard-int-xd)# report flow refresh-interval <value> seconds
```

Enable the drop report.

```
switch(config-tele-postcard-int-xd)# report drop
```

Enable the queue report.

```
switch(config-tele-postcard-int-xd)# report queue
```

Configure the queue depth threshold. By default, EOS uses 2 percent.

```
switch(config-tele-postcard-int-xd) # report queue depth 10 percent
```

Configure the switch hop latency threshold. By default, EOS uses 2048 ns.

```
switch(config-tele-postcard-int-xd) # report queue latency 1024 nanoseconds
```

Configure the queue report suppression limits. By default, EOS uses 1000 reports/sec per queue.

```
switch(config-tele-postcard-int-xd) # report queue rate-limit 1000 reports-per-second
```

Configure the unique ID of a switch.

```
switch(config-tele-postcard-int-xd) # device id 25
```

Exit the mode to commit the changes.

```
switch(config-tele-postcard-int-xd) # exit
```

## Show Commands

This example displays the mapping between drop reason text and drop reason code.

```
switch(config) # show platform barefoot int drop codes
Code Reason

1 Ingress STP blocked
2 Ingress invalid VLAN
```

This command shows the current sequence number of the INT-XD reports. Sequence number is incremented every time an INT-XD report is sent. It shows the sequence number in HEX format.

```
switch(config) # show platform barefoot registers seqNumber
```

## Configuration Considerations

- EOS does not support specific flow watchlist to filter flows.
- Uses a 5-tuple of an outer header for tracking the flows.
- EOS does not support collector reachability through overlay networks.
- Does not export packets sent to the CPU to the collector.
- EOS does not support collector reachability over non default vrf .
- EOS does not support collector reachability through the out of band management port.
- Only exports unicast packet tail drops to collectors.
- Sends INT reports to a single collector reachable via IPv4.

## 21.3.6 Sampled Flow Tracking Configuration Examples

This section describes the command configurations required to configure sampled flow tracking.

### 21.3.6.1 Sampled Flow Tracking Basic Configuration

The following commands enable a basic configuration.

- 
1. Enable configuration mode for the sampled flow tracking on a device.

```
switch(config)# flow tracking sampled
```

2. Configure a sampled flow tracker for a device.

```
switch(config-flow-tracking-sampled)# tracker ftr1
```

3. Configure an exporter for the specific tracker.

```
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
```

4. Configure the collector for the specific exporter.

```
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# collector 172.31.22.131
```

5. Configure the local source **interface Ethernet1** for the specific exporter.

```
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# local interface Ethernet1
```

6. Enable sampled flow tracking.

```
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# no shutdown
```

7. Configure the **interface Ethernet2** for the specific exporter.

```
switch(config)# interface Ethernet2
```

8. Configure the sampled flow tracker on **interface Ethernet2**.

```
switch(config)# interface Ethernet2
switch(config-if-Et2)# flow tracker sampled ftr1
```

## 21.3.7 Sampled Flow Tracking Commands

This section contains descriptions of Sampled Flow Tracking commands.

### Configuration Commands

- [collector](#)
- [dscp](#)
- [exporter](#)
- [flow tracking sampled](#)
- [format ipfix version](#)
- [local interface](#)
- [record export on inactive timeout](#)
- [record export on interval](#)
- [sample](#)
- [shutdown \(sampled flow tracking\)](#)
- [template interval](#)
- [tracker](#)

### Interface Configuration Command

- [flow tracker sampled](#)

## Privileged EXEC Command

- `clear flow tracking sampled counters`

## Sampled Flow Tracking Display Commands

- `show flow tracking sampled`
- `show flow tracking sampled counters`
- `show flow tracking sampled flow-table`
- `show flow tracking sampled ipfix options-table`
- `show flow tracking sampled ipfix template`

### 21.3.7.1 `clear flow tracking sampled counters`

The `clear flow tracking sampled counters` command clears the flow tracking counters for all trackers, a specified tracker, or a specified tracker and exporter.

#### Command Mode

Privileged EXEC

#### Command Syntax

```
clear flow tracking sampled counters [tracker tracker_name [exporter exporter_name]]
```

#### Parameters

- **tracker *tracker\_name*** Specifies the flow tracker.
- **exporter *exporter\_name*** Specifies the exporter.

#### Example

This command clears the flow counters for the tracker **ftr1** and exporter **exp1**.

```
switch# clear flow tracking sampled counters tracker ftr1 exporter exp1
switch#
```

### 21.3.7.2 `collector`

The `collector` command configures a collector to receive flow records from a specified exporter.

The `no collector` and `default collector` commands remove the configured collector from **running-config**.

#### Command Mode

Sampled Flow Tracking Exporter Configuration

#### Command Syntax

```
collector {ipv4_address | ipv6_address} [port port_number]
no collector {ipv4_address | ipv6_address} [port port_number]
default collector {ipv4_address | ipv6_address} [port port_number]
```

#### Parameters

- 
- **ipv4\_address** Specifies the IPv4 address of the collector.
  - **ipv6\_address** Specifies the IPv6 address of the collector.
  - **port port\_number** Specifies the port number for the collector. Values range from **1** to **65535**. The default value is **4739**.

### Example

These commands configure a collector for the IPv4 address **192.0.2.0** and collector port number **10**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# collector 192.0.2.0 port 10
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# exit
switch(config-ftr-sampled-tr-ftr1)# exit
switch(config-flow-tracking-sampled)# exit
switch(config)#

```

#### 21.3.7.3 dscp

The **dscp** command configures the Differentiated Services Code Point (DSCP) value for a specific exporter.

The **no dscp** and **default dscp** commands reset the DSCP value to the default of 0.

#### Command Mode

Sampled Flow Tracking Exporter Configuration

#### Command Syntax

```
dscp dscp_value
no dscp dscp_value
default dscp dscp_value
```

#### Parameter

**dscp\_value** the DSCP value assigned to the exporter. Value ranges from **0** to **63**. Default value is **0**.

### Example

These commands configure a DSCP value of **10** for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# dscp 10
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# exit
switch(config-ftr-sampled-tr-ftr1)# exit
switch(config-flow-tracking-sampled)# exit
switch(config)#

```

#### 21.3.7.4 exporter

The **exporter** command places the switch in sampled flow tracking exporter configuration mode for the specified exporter and creates the exporter if it does not yet exist.

The **no exporter** and **default exporter** commands remove the specific exporter from **running-config**.

#### Command Mode

## Sampled Flow Tracking Tracker Configuration

### Command Syntax

```
exporter exporter_name
no exporter exporter_name
default exporter exporter_name
```

### Parameter

***exporter\_name*** the name of the exporter.

### Example

These commands create exporter ***exp1*** for the flow tracker ***ftr1*** and place the switch in configuration mode for that exporter.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)#exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1) #
```

---

### 21.3.7.5 flow tracker sampled

The **flow tracker sampled** command configures an interface to be part of a flow tracker. An interface can belong to only one flow tracker.

The **no flow tracker sampled** and **default flow tracker sampled** commands remove the specified interface from the specified tracker.

#### Command Mode

Interface-Ethernet Configuration

#### Command Syntax

```
flow tracker sampled tracker_name
no flow tracker sampled tracker_name
default flow tracker sampled tracker_name
```

#### Parameter

**tracker\_name** the name of the flow tracker to which the interface is to be added.

#### Example

This command configures **Interface ethernet 1** to participate in the flow tracker **ftr1**.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# flow tracker sampled ftr1
switch(config-if-Et1) #
```

---

### 21.3.7.6 flow tracking sampled

The **flow tracking sampled** command places the switch in sampled flow tracking configuration mode. Sampled flow tracking configuration mode is a group-change mode; changes made in a group-change mode are saved by exiting the mode.

The **no flow tracking sampled** and **default flow tracking sampled** commands remove all sampled flow tracking configuration from **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
flow tracking sampled
no flow tracking sampled
default flow tracking sampled
```

#### Parameters

- **abort** - Exits mode without saving changes.
- **exit** - Exits mode and saved changes.
- **sample** - Configures sample parameters.
- **shutdown (sampled flow tracking)** - Enables or disables sampled flow tracking
- **tracker** - Configures a flow tracker.

## Example

This command places the switch in the ***sampled flow tracking*** configuration mode.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled) #
```

### 21.3.7.7 format ipfix version

The **format ipfix version** command configures the IPFIX version and maximum packet size for a specific exporter.

The **no format ipfix version** and **default format ipfix version** commands remove the previously configured IPFIX version and the maximum packet size value from ***running-config***.

#### Command Mode

Sampled Flow Tracking Configuration

#### Command Syntax

```
format ipfix version ipfix_version [max-packet-size max-packet-size value]
no format ipfix version ipfix_version [max-packet-size]
default format ipfix version ipfix_version [max-packet-size]
```

#### Parameters

- ***ipfix\_version*** the IPFIX version. Default value is **10**.
- **max-packet-size *max-packet-size value*** the IPFIX maximum packet size. Value ranges from **512** to **65472**. Default value is **9152**.

## Example

These commands configure an IPFIX version of **10** and a maximum packet size of **854** for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled) # tracker ftr1
switch(config-ftr-sampled-tr-ftr1) # exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1) # format ipfix version 10 max-packet-size 854
```

### 21.3.7.8 local interface

The **local interface** command configures the local source interface for the specific exporter.

The **no local interface** and **default local interface** commands remove the local interface for the specific exporter from ***running-config***.

#### Command Mode

Sampled Flow Tracking Configuration

#### Command Syntax

```
local interface interface
no local interface
default local interface
```

## Parameters

**interface** Interface type and numbers. Options include:

- **Ethernet *eth\_num*** displays the information of the specified Ethernet interface. The value ranges from **1** to **64**.
- **Loopback *lb\_num*** displays the information of the specified loop back interface. The value ranges from **0** to **2100**.
- **Management *m\_num*** displays the information of the specified Management interface. The management port number ranges from **1** to **2**.
- **Port-Channel *pc\_num*** displays the interface or sub-interface information of the specified port channel. The interface and sub-interface values of port channel ranges from **1-1000** and **1-2000, 1-4094** respectively.
- **Tunnel *t\_num*** displays the information of the specified tunnel. The value ranges from **0** to **255**.
- **Vlan *vlan\_num*** displays the information of the specified VLAN interface. The value ranges from **1** to **4094**.

## Example

These commands configure the local source **interface Ethernet1** for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# local interface Ethernet1
```

### 21.3.7.9 record export on inactive timeout

The **record export on inactive timeout** command configures the interval at which inactive flow records time out and are exported for a flow tracker.

The **no record export on inactive timeout** and **default record export on inactive timeout** commands remove the timeout interval from **running-config**.

#### Command Mode

Sampled Flow Tracking Configuration

#### Command Syntax

```
record export on inactive timeout timeout_value
no record export on inactive timeout
default record export on inactive timeout
```

#### Parameters

**timeout\_value** the flow record inactive export timeout value in milliseconds. Value ranges from **3000** to **900000**. The default value is **15000** milliseconds.

## Example

These commands configure an inactive record interval of **6000** for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# record export on inactive timeout 6000
```

### 21.3.7.10 record export on interval

The `record export on interval` command configures the interval at which active flow records are exported for a flow tracker.

The `no record export on interval` and `default record export on interval` commands remove the interval from *running-config*.

#### Command Mode

Sampled Flow Tracking Configuration

#### Command Syntax

```
record export on interval interval_value
no record export on interval
default record export on interval
```

#### Parameter

***interval\_value*** the flow record export interval in milliseconds. Value ranges from **5000** to **36000000**. The default value is **300000** milliseconds.

#### Example

These commands configure an active record interval of **9000** for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# record export on interval 9000
```

---

### 21.3.7.11 sample

The **sample** command enables the sample rate for a specific sampled flow tracker.

The **no sample** and **default sample** commands remove the sample rate configured for a specific sampled flow tracker from **running-config**.

#### Command Mode

Sampled Flow Configuration

#### Command Syntax

```
sample sample_rate
```

```
no sample
```

```
default sample
```

#### Parameter

**sample\_rate** the sample flow tracking rate to be assigned for a sampled flow tracker. Value ranges from **1024** to **16777216**. Default value is **1048576**.

#### Example

These commands configure a sample rate of **2056** for the sampled flow tracker.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# sample 2056
```

---

### 21.3.7.12 show flow tracking sampled

The **show flow tracking sampled** command displays information about the status of a specific tracker and the status of a specified exporter within that tracker. If no tracker is specified in the command, then all information about all trackers is displayed.

#### Command Mode

EXEC

#### Command Syntax

```
show flow tracking sampled [tracker tracker_name [exporter exporter_name]]
```

#### Parameters

- **tracker *tracker\_name*** the specific flow tracker.
- **exporter *exporter\_name*** the specific exporter within the tracker.

#### Example

This command displays the status information of the tracker **ftr1** and the exporter **exp1**.

```
switch# show flow tracking sampled tracker ftr1 exporter exp1
Flow tracking status
Type: Sampled
Running: yes
Sample rate: 1024
Tracker: ftr1
Active interval: 30000ms
Inactive timeout: 120000ms
Groups: IPv4, IPv6
```

```

Exporter: exp1
VRF: default
Local interface: Management1 (172.30.150.179)
Export format: IPFIX version 10, MTU 1500
DSCP: 48
Template interval: 3600000ms
Collectors:
172.31.22.131 port 4739
Active interfaces:
Et1

```

### 21.3.7.13 show flow tracking sampled counters

The **show flow tracking sampled counters** command displays information about the flow tracking counters of a specific tracker and the counters of a specified exporter within that tracker.

#### Command Mode

EXEC

#### Command Syntax

```
show flow tracking sampled counters [tracker tracker_name [exporter exporter_name]]
```

#### Parameters

- **tracker *tracker\_name*** the specific flow tracker.
- **exporter *exporter\_name*** the specific exporter within the tracker.

#### Example

This command displays the flow tracking counter information of the tracker **ftr1** and the exporter **exp1**.

```

switch# show flow tracking sampled counters tracker ftr1 exporter exp1
Tracker: ftr1
 1 flows, 22 RX packets
 Flows created: 1, expired: 0
 Group: IPv4
 1 flows, 22 RX packets
 Group: IPv6
 0 flows, 0 RX packets
 Exporter: exp1 (IPFIX)
 Collector: 172.31.24.133 port 4739
 52 messages, last sent 0:00:27 ago
 0 flow records
 2350 options data records, last sent 0:00:27 ago
 6 templates, last sent 0:12:27 ago
 Collector: 172.31.22.131 port 4739
 52 messages, last sent 0:00:27 ago
 0 flow records
 2350 options data records, last sent 0:00:27 ago
 6 templates, last sent 0:12:27 ago

```

---

#### 21.3.7.14 show flow tracking sampled flow-table

The **show flow tracking sampled flow-table** command displays information about the active flows maintained in the EOS.

##### Command Mode

EXEC

##### Command Syntax

```
show flow tracking sampled flow-table [detail | dst-ip | dst-port | group | interface | protocol | src-ip | src-port | tracker | vlan | vrf]
```

##### Parameters

- **detail** displays detailed flow records.
- **dst-ip** displays flow records based on destination IPv4 or IPv6 address.
- **dst-port** displays flow records based on a specified destination port.
- **group** displays flow records based on IPv4 or IPv6 flow groups.
- **interface** displays flow records based on ingress interface.
- **protocol** displays flow records based on the flow IP protocol.
- **src-ip** displays flow records based on source IPv4 or IPv6 address.
- **src-port** displays flow records based on a specified source port.
- **tracker** displays flow records based on flow tracker.
- **vlan** displays flow records based on a specified flow VLAN ID.
- **vrf** displays flow records based on flow VRF.

##### Examples

- This command displays information about the active flows on the device.

```
switch# show flow tracking sampled flow-table
Tracker: ftr1, Flows: 1
 Group: IPv4, Flows: 1
 VRF VLAN Source Destination Protocol Start Time Pkts Bytes
 --- ----- ----- ----- ----- ----- -----
 red 42 10.10.1.1:0 10.20.1.2:0 UDP 2019-04-18 15:06:50 7 700
```

- This command displays detailed information about the active flows on the device.

```
switch# show flow tracking sampled flow-table detail
Tracker: ftr1, Flows: 1
 Group: IPv4, Flows: 1
 Flow: UDP 10.10.1.1:0 - 10.20.1.2:0, VRF: red, VLAN: 42
 Start time: 2019-04-18 15:06:50.268734, Last packet time: 2019-04-18 15:07:03.607900
 Packets: 15, Bytes: 1500, TOS: 0, TCP flags: none
 Source MAC: 001c.73ee.bfe4, Destination MAC: 001c.7374.3b85
 Ingress Interface: 'Ethernet1', Egress VLAN: routed, Egress Interface: CPU
 Next hop: unknown, BGP next hop: unknown (AS unknown), Source AS: unknown
 Source prefix length: 24, Destination prefix length: 32
```

### 21.3.7.15 show flow tracking sampled ipfix options-table

The **show flow tracking sampled ipfix options-table** command displays information about the sampled IPFIX options table available.

#### Command Mode

EXEC

#### Command Syntax

```
show flow tracking sampled ipfix options-table [tracker | flow-key | flow-tracker | interface | vrf]
```

#### Parameters

- **tracker** displays the output for a specific flow tracker.
- **flow-key** displays the flow keys options table.
- **flow-tracker** displays the flow tracker options table.
- **interface** displays the interface options table.
- **vrf** displays the VRF options table.

#### Example

This command displays the sampled IPFIX options table for the tracker **ftr1**.

```
switch# show flow tracking sampled ipfix options-table
Tracker: ftr1
 Observation domain: ftr1, ID: 1
 Active interval: 30sec
 Inactive timeout: 120sec
 Selector algorithm: random(3)
 Sampling: 1/1024
 Flow tracking type: sampled(1)
 VRF Table, Template ID: 256, Scope: ingressVRFID
 VRF ID VRF Name

 0 default
 1 red
 16777215
 Interface Table, Template ID: 257, Scope: ingressInterface
 Interface ID Interface Name

 0 unknown
 3013 Ethernet1
 3014 Ethernet2
 1073741823 CPU
 1073741824 discard
 1074029945 Ethernet3/36/1.1
 1074292089 Ethernet3/36/1.2
 2147483648 multicast
 Flow Keys Table, Template ID: 258, Scope: templateId
 Template ID Flow Key Indicator

 261 0x7f
 262 0x7f
```

---

### 21.3.7.16 show flow tracking sampled ipfix template

The **show flow tracking sampled ipfix template** command displays information about the exported IPFIX data templates and options templates.

#### Command Mode

EXEC

#### Command Syntax

```
show flow tracking sampled ipfix template [data | options | tracker]
```

#### Parameters

- **data** displays the data templates.
- **options** displays the flow options template.
- **tracker** displays the flow tracker template.

#### Example

This command displays the sampled IPFIX options table for the tracker **ftr1**.

```
switch# show flow tracking sampled ipfix template
Tracker: ftr1
 Data Template, Group: IPv4, Fields: 26, Template ID: 261
 ingressVRFID (234), 4 bytes
 vlanId (58), 2 bytes
 sourceIPv4Address (8), 4 bytes
 destinationIPv4Address (12), 4 bytes
 protocolIdentifier (4), 1 bytes
 sourceTransportPort (7), 2 bytes
 destinationTransportPort (11), 2 bytes
 sourceMacAddress (56), 6 bytes
 postDestinationMacAddress (57), 6 bytes
 octetDeltaCount (1), 8 bytes
 packetDeltaCount (2), 8 bytes
 flowStartMilliseconds (152), 8 bytes
 flowEndMilliseconds (153), 8 bytes
 flowEndReason (136), 1 bytes
 tcpControlBits (6), 2 bytes
 ingressInterfaceType (368), 4 bytes
 ingressInterface (10), 4 bytes
 postVlanId (59), 2 bytes
 egressInterface (14), 4 bytes
 ipClassOfService (5), 1 bytes
 bgpSourceAsNumber (16), 4 bytes
 bgpDestinationAsNumber (17), 4 bytes
 bgpNextHopIPv4Address (18), 4 bytes
 ipNextHopIPv4Address (15), 4 bytes
 sourceIPv4PrefixLength (9), 1 bytes
 destinationIPv4PrefixLength (13), 1 bytes

<-----OUTPUT OMITTED FROM EXAMPLE----->
```

### 21.3.7.17 shutdown (sampled flow tracking)

The **shutdown** command disables sampled flow tracking for the specific exporter.

The **no shutdown** command enables sampled flow tracking for the specific exporter.

#### Command Mode

Sampled Flow Tracking Configuration

#### Command Syntax

```
shutdown
no shutdown
default shutdown
```

#### Example

These commands enable sampled flow tracking for the specific exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# local interface Ethernet1
switch(config-ftr-sampled-tr-ftr1-exp-exp1)# no shutdown
```

---

### 21.3.7.18 template interval

The **template interval** command configures the interval at which templates are exported for a specific exporter. The default template interval is **3600000** milliseconds.

The **no template interval** and **default template interval** commands reset the interval rate to the default.

#### Command Mode

Sampled Flow Tracking Configuration

#### Command Syntax

```
template interval interval
no template interval
default template interval
```

#### Parameter

**interval** the interval rate in milliseconds. The value ranges between **5000** and **3600000** milliseconds. The default rate is **3600000** milliseconds.

#### Example

This command configures the interval of **3400000** milliseconds for the exporter **exp1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)# tracker ftr1
switch(config-ftr-sampled-tr-ftr1)# exporter exp1
switch(config-ftr-sampled-tr-exp-ftr1-exp1)# template interval 3400000
```

### 21.3.7.19 tracker

The **tracker** command configures a sampled flow tracker for a device.

The **no tracker** and **default tracker** commands remove the sampled flow tracker from the **running config**.

#### Command Mode

Sampled Flow Configuration

#### Command Syntax

```
tracker tracker_name
no tracker tracker_name
default tracker tracker_name
```

#### Parameter

**tracker\_name** the flow tracker name.

#### Example

These commands configure the sampled flow tracker **ftr1**.

```
switch(config)# flow tracking sampled
switch(config-flow-tracking-sampled)#tracker ftr1
```

---

## 21.4 sFlow

This chapter describes Arista's implementation of sFlow, including configuration instructions and command descriptions. Topics covered by this chapter include the following:

- [sFlow Conceptual Overview](#)
- [Configuring sFlow](#)
- [Egress Sampling for sFlow Interfaces](#)
- [sFlow Subinterfaces](#)
- [sFlow Commands](#)

### 21.4.1 sFlow Conceptual Overview

#### 21.4.1.1 sFlow Technology

Sampled Flow (sFlow) provides a multi-vendor sampling technology that continuously monitors application level traffic flow at wire speed simultaneously on all interfaces. sFlow provides gigabit speed quantitative traffic measurements without impacting network performance.

sFlow has the following network traffic monitoring characteristics:

- sFlow provides a statistical sampling technology designed to be deployed on all ports within a network to provide end-to-end visibility.
- sFlow exports packet samples and topology meta data to a centralized collector application.
- sFlow scales and operates on all switch ports simultaneously.
- EOS implements sFlow on all switches, without requiring additional memory or CPU and does not impact data plane forwarding.

An sFlow configuration consists of the following:

- sFlow agents, embedded on network equipment monitoring traffic and generating data.
- sFlow collectors that receive and analyze sFlow data.

Arista switches include an sFlow agent that monitors ingress data through all Ethernet interfaces.

#### 21.4.1.1.1 sFlow Agents

The sFlow agent runs a software process as part of the network management software within an Arista switch. It combines interface counters and flow samples into sFlow datagrams sent to an sFlow collector. Packets typically include flow samples and state information of the forwarding/routing table entries associated with each sample. sFlow agents gather additional data from entries originated by BGP.

When packaging data into datagrams, the sFlow Agent performs minimal processing. Immediate data forwarding minimizes agent memory and CPU requirements.

#### 21.4.1.1.2 sFlow Collector

An sFlow collector runs software that analyzes and reports network traffic. Collectors receive flow samples and counter samples as sFlow datagrams from sFlow agents.

Arista switches reference the IP address and UDP port of collectors as configurable settings through a CLI command. Arista switches do not include sFlow collector software.

#### 21.4.1.1.3 sFlow Data

The sFlow Agent uses two forms of sampling: statistical packet-based sampling of switched flows and time-based sampling of network interface statistics.

- **Switched flow sampling** - Takes a sample by either copying the packet header or extracting feature data.
- **Interface statistics sampling** - Counter sampling extracts statistics by periodically polling each data source on the device.

sFlow implements flow sampling and counter sampling as part of an integrated system. An sFlow datagram incorporates both sample types.

#### 21.4.1.2 Arista sFlow Implementation

Arista switches provide a single sFlow agent instance that samples ingress traffic from all Ethernet and port channel interfaces. The switch provides two levels of settings for enabling sFlow:

- **Global** - Settings that enable packet sampling on the entire switch.
- **Interface** - Settings that control sampling on individual interfaces when globally enabling sFlow.

The sFlow default settings include the following:

- **Global** - Disable sFlow and BGP sFlow export globally.
- **Ethernet and Port Channel Interfaces** - Enabling sFlow globally impacts all interfaces. When enabled globally, BGP sFlow export impacts all interfaces.

When globally enabled, the switch performs sFlow polling. The CLI provides commands that globally turn off sampling while counter-polling remains enabled. Sample enabling is not controllable on individual interfaces.

The switch sends sFlow datagrams to the collector at an IP address specified by a global configuration command. If no collector destination exists, the switch samples data without transmitting the resulting datagrams.

Although the CLI enforces the configured sampling rate limit, sFlow may drop samples if it cannot handle the number of samples received over a specified period. Under normal operation, the maximum packet sample rate is one per 16384 packets. The CLI allows for higher sampling rates by using the **dangerous** keyword.

Configure the switch to allow the routing agent to export BGP information to the sFlow agent. When enabling BGP sFlow export, sFlow adds BGP information to packets with BGP route destinations.

The following lists describe sFlows sampling behavior relative to different packet types.

- Sampled Packets
  - CPU
  - IP Options
  - L3 MTU violations
  - Flooded packets
  - Multicast packets
  - IGMP packets
  - LACP frames
  - PAUSE frames
  - STP BPDUs
  - BPDU dropped packets

- STP blocked ports

 **Note:** Not sampled on 7300X3, 7320X, 7358, 7368, 7388, CCS-710P, CCS-720DF, CCS-720DP, CCS-720DT, CCS-720XP, CCS-722XPM, CCS-750, DCS-7010TX, DCS-7050X3, DCS-7050X4, DCS-7060X, DCS-7060X2, DCS-7060X4, DCS-7060X5, DCS-7260X, DCS-7260X3, DCS-7300X

- PIM hello packets
- VLAN tag violation dropped packets

 **Note:** Not sampled on 7300X3, 7320X, 7358, 7368, 7388, CCS-710P, CCS-720DF, CCS-720DP, CCS-720DT, CCS-720XP, CCS-722XPM, CCS-750, DCS-7010TX, DCS-7050X3, DCS-7050X4, DCS-7060X, DCS-7060X2, DCS-7060X4, DCS-7060X5, DCS-7260X, DCS-7260X3, DCS-7300X

- Packets not sampled:
  - L2 MTU violations
  - LLDP frames
  - CRC error frames
  - ACL dropped packets

 **Note:** Use the `sflow sample drop include reason acl` command to sample these packets on 7289, 7500R3, DCS-7020, DCS-7130, DCS-7132, DCS-7280R, DCS-7280R2, DCS-7280R3, DCS-7500R, DCS-7500R2, DCS-7500R3, DCS-7800, DCS-7800R3, DCS-7280R, DCS-7280R2, DCS-7500R, DCS-7500R2, DCS-7020R, DCS-7280R3, DCS-7500R3, DCS-7800R3

#### 21.4.1.3 sFlow and Mirroring

sFlow and Mirroring supports using the same interface for a mirroring session and sFlow at the same time. When configured on the same interface, sFlow does not support TAP Aggregation. Enabling TAP Aggregation mode configures the interface as a source for a mirroring session, and sFlow only mirrors packets. No sFlow samples produced.

The following switches support sFlow and Mirroring:

- DCS-7280R
- DCS-7280R2
- DCS-7280E
- DCS-7500R
- DCS-7500R2
- DCS-7500E
- DCS-7050X
- DCS-7060X
- DCS-7250X
- DCS-7260X
- DCS-7300X

However, the following switches have a limitation:

- DCS-7280R
- DCS-7280R2
- DCS-7280E

- DCS-7500R
- DCS-7500R2
- DCS-7500E

When configuring a mirroring session and sFlow on a same interface for the above devices, the following packet types do not sample though they sample with only sFlow.

- STP BPDUs
- LACP frames
- LLDP frames
- OSPF packets
- PIM HELLO packets
- Packets dropped due to VLAN violations

#### **21.4.1.4 Hardware Accelerated sFlow**

Compatible platforms support hardware-accelerated sFlow. Without hardware acceleration, the software performs all sFlow processing, and performance depends on the capabilities of the host CPU. Aggressive sampling rates also decrease the processing time available for other EOS applications.

With hardware acceleration, hardware performs all sFlow processing using specialized chips called accelerators. These accelerators process sampled packets and send out sFlow datagrams in the same manner as the software agent. The CPU has little involvement and dedicates the chips to sFlow with higher performance and the CPU has more availability for other tasks, even with high sampling rates.

The following switches support hardware-accelerated sFlow:

- DCS-7280R3
- DCS-7280SR2A-48YC6
- DCS-7280CR2-60
- DCS-7280CR2A-60
- DCS-7280CR2K-60
- DCS-7280CR2-30
- DCS-7280CR2A-30
- DCS-7280SRAM-48C6
- DCS-7280SR2K-48C6
- DCS-7500R3
- DCS-7500R2A-36CQ-LC
- DCS-7500R2AK-36CQ-LC
- DCS-7500R2AM-36CQ-LC
- DCS-7500R2AK-48YCQ-LC
- DCS-7800R3

The following switches have limitations:

- DCS-7280R
- DCS-7280R2
- DCS-7280E
- DCS-7500R
- DCS-7500R2
- DCS-7500E

Before enabling hardware-accelerated sFlow, the following requirements must be fulfilled:

- sFlow enabled globally.
- Routing must be enabled in any VRF. This is required for sFlow datagrams to be routed to the collector(s).

The following command enables or disables hardware-accelerated sFlow in configuration mode.

```
switch(config)# [no|default] sflow hardware acceleration
```

The following command disables hardware-accelerated sFlow on a particular LineCard.

```
switch(config)# no sflow hardware acceleration module Linecard3
```

The following command reverts hardware-accelerated sFlow on a particular LineCard.

```
switch(config)# sflow hardware acceleration module Linecard3
```

## Examples

- The following example enables routing on the switch, activates sFlow, and enables hardware acceleration globally, but forces software sFlow on Linecard3.

```
switch(config)# ip routing
switch(config)# sflow run
switch(config)# sflow hardware acceleration
switch(config)# sflow source 10.10.10.1
switch(config)# sflow destination 10.10.10.2
switch(config)# sflow hardware acceleration sample 1024
switch(config)# no sflow hardware acceleration module Linecard3
```

- The following example displays the IPv6 configuration. Hardware accelerated sFlow enables either IPv4 or IPv6 collectors. IPv6 configuration takes precedence over IPv4 configuration and disables IPv4 collectors.

```
switch(config)# ipv6 unicast-routing
switch(config)# ip routing
switch(config)# sflow run
switch(config)# sflow hardware acceleration
switch(config)# sflow source-interface Ethernet1/1
switch(config)# sflow destination 10.10.10.2
switch(config)# sflow hardware acceleration sample 1024
switch(config)# no sflow hardware acceleration module Linecard3
```

- The command **show sflow hardware status** displays the current status of hardware acceleration for sFlow for fixed system.

```
switch(config)#show sflow hardware status
Status

Hardware Acceleration On: No
 - sFlow must be enabled
 - sFlow hardware acceleration must be enabled in the CLI
 - routing must be enabled in any VRF
Sample Rate: None
```

- The command **show sflow hardware status** displays the current status of hardware acceleration for sFlow for modular system.

```
switch(config)#show sflow hardware status
Status

Hardware Acceleration On: Yes
Sample Rate: 1048576
 sFlow Mode
Module Active Configured Has sFlow accelerators
----- -----
Linecard3 Software Hardware-accelerated No
Linecard4 Software Hardware-accelerated No
Linecard5 Hardware-accelerated Hardware-accelerated Yes
```

|           |                      |                      |    |
|-----------|----------------------|----------------------|----|
| Linecard6 | Hardware-accelerated | Hardware-accelerated | No |
|-----------|----------------------|----------------------|----|

- The command **show sflow hardware counters** displays counters specific to sFlow acceleration.

```
switch(config)# show sflow hardware counters

SflowAccelFpga7:0

Incoming Packet Count : 0
Outgoing Sflow Datagram Count : 0
Outgoing Flow Sample Count : 0
Incoming Processed Packet Count : 0
Receive Packet Drop Count : 0
Packet Truncated Count : 0
Incoming Packet Error Count : 0
Outgoing Processed Datagram Count : 0
Sample Pool : 0

SflowAccelFpga7:1

Incoming Packet Count : 0
Outgoing Sflow Datagram Count : 0
Outgoing Flow Sample Count : 0
Incoming Processed Packet Count : 0
Receive Packet Drop Count : 0
Packet Truncated Count : 0
Incoming Packet Error Count : 0
Outgoing Processed Datagram Count : 0
Sample Pool : 0

Total

Incoming Packet Count : 0
Outgoing Sflow Datagram Count : 0
Outgoing Flow Sample Count : 0
Incoming Processed Packet Count : 0
Receive Packet Drop Count : 0
Packet Truncated Count : 0
Incoming Packet Error Count : 0
Outgoing Processed Datagram Count : 0
Sample Pool : 0
```

- The command **show sflow hardware accelerators** displays a list of all hardware accelerators currently present in the system.

```
switch(config)#show sflow hardware accelerators
Slice sFlow Accelerator Type PCI Address Direct Connections

Linecard7 SflowAccelFpga7:0 halo 0000:85:00.0 Jericho7/0
Linecard9 SflowAccelFpga9:0 halo 0000:a6:00.0 Jericho9/0
```

- The command **show sflow hardware mapping** displays hardware accelerator performs sFlow processing for each switch chip in the system. Hardware acceleration needs to be enabled and running, otherwise the output of the command is empty.

```
switch(config)#show sflow hardware mapping
Chip sFlow Accelerator Direct Connection

Jericho3/0 SflowAccelFpga7:0 False
Jericho3/1 SflowAccelFpga7:0 False
Jericho4/0 SflowAccelFpga9:0 False

Jericho6/1 SflowAccelFpga9:0 False
Jericho7/0 SflowAccelFpga7:0 True
Jericho9/0 SflowAccelFpga9:0 True
```

## 21.4.2 Configuring sFlow

Implementing sFlow on an Arista switch consists of configuring the following agent parameters:

- Collector location address
- Agent source address
- Polling interval
- Sampling rate

Optionally, sFlow can be configured to include output interface and traffic class information in samples using the [sflow sample](#) command, and to include BGP information in samples whose destination is a BGP route using the [sflow extension bgp](#) command.

After configuring the sFlow agent, enable sFlow globally to initiate sampling sFlow on the switch.

### Platform-specific Considerations

Enabling BGP sFlow export on Arad platform switches, DCS-7280E and DCS-7500E, adds BGP information to some sFlow packets with ECMP destinations.

DCS-7500E switches use actual hardware egress port information in sFlow packets. All other platforms use software simulation to determine the egress port.

### Configuring the Collector Location

The [sflow destination](#) command specifies the IP address and UDP port of an sFlow collector. The switch supports multiple collectors.

#### Example

This command configures the switch to send sFlow data to collectors at **192.0.2.1**, port **6100** and **2001:0db8::2** port **6343** (the default sFlow port).

```
switch(config) # sflow destination 192.0.2.1 6100
switch(config) # sflow destination 2001:0db8::2
switch(config) #
```

### Configuring the Agent Source Address

The [sflow source](#) command specifies the source address that the switch places in all sFlow datagrams that it sends to the collector. This address is normally set to an IP address configured on the switch.

#### Example

This command configures **2001:0db8::21** as the sFlow source address.

```
switch(config) # sflow source 2001:0db8::21
switch(config) #
```

The [sflow source-interface](#) command can be alternatively used to specify the interface from which an IP address is derived that the switch places in all sFlow datagrams that it sends to the collector. This address is normally set to an IP address configured on the switch.

#### Example

This command configures **interface vlan 25** as the sFlow source interface. The switch enters the IP address for **vlan 25** in the source field of sFlow datagrams.

```
switch(config) # sflow source-interface vlan 25
switch(config) #
```

**running-config** cannot simultaneously contain [sflow source](#) and [sflow source-interface](#) commands.

### Configuring the Polling Interval

The [sflow polling-interval](#) command specifies the interval for sending counter data to the sFlow collector. The default interval is two seconds.

#### Example

This command configures the switch to send sFlow data every **10** seconds.

```
switch(config)# sflow polling-interval 10
switch(config) #
```

### Configuring the Sampling Rate and Sample Contents

The [sflow sample](#) command sets the packet sampling rate. Packets are sampled at random intervals to avoid inaccurate sampling of periodic events. A rate of **16384** corresponds to an average sample of one per **16384** packets. The default rate is **1048576**.

#### Example

This command configures the sFlow sampling rate as **65536** (one per **65536** packets).

```
switch(config)# sflow sample 65536
switch(config) #
```

The [sflow sample](#) command can also optionally configure sample packets to include information about the traffic class of the sample. Traffic class is communicated by rewriting the DSCP field in the sample packet.

By default, samples include information about the output interface. To remove this information, use the [sflow sample output interface](#) command.

#### Example

These commands configure sFlow to include traffic class information in samples but to exclude output interface data.

```
switch(config)# no sflow sample output interface
switch(config)# sflow sample rewrite dscp
switch(config) #
```

### Configuring the sFlow Datagram Size

The default datagram size, 1400, may drop with a Maximum Transmission Unit (MTU) threshold configured. Configure the default maximum datagram payload size of 1400 bytes to a size from 200 to 1500 bytes to avoid fragmentation.

**Note:** Only software sFlow supports this feature.

Use the following command to configure the sFlow datagram size as **1500**:

```
switch(config)# sflow datagram size maximum 1500
```

## Enabling BGP sFlow Export

The [sflow extension bgp](#) command enables BGP sFlow export. When it is enabled, the routing agent will export the BGP routing table and autonomous system path information to the sFlow agent. When sFlow receives a sampled packets whose destination is a BGP route, it will look up the following additional BGP routing information and include it in the sample:

- next hop IP
  - AS numbers
  - AS system path to the destination
  - communities
  - local pref

On Arad platform switches (DCS-7280E and DCS-7500E), BGP sFlow export will also add the above BGP information to sample packets with ECMP destination routes unless they exit the switch via a trunk port or subinterface. When egress port is a trunk port or subinterface, the sample packet will only include AS path information from the first path of the ECMP route and a BGP next hop of **0**.

On all other switch platforms, ECMP destination routes will include AS path information from the first path, but will identify the BGP next hop as **0**.

**Note:** A BGP instance must be configured on the switch for BGP sFlow export to operate. See the Border Gateway Protocol (BGP) chapter for details.

## Example

These commands configure a BGP instance in AS 50 and enable BGP sFlow export globally.

```
switch(config) # router bgp 50
switch(config-router-bgp) # exit
switch(config) # sflow extension bgp
switch(config) #
```

## Extended Switch and Router Information

By default, extended switch and router information is added to sFlow sample packets.

Extended switch information includes the following:

- source and destination VLANs and priorities.

Extended router information includes the following:

- IP version and address of next-hop router.
  - source and destination mask lengths.

The **no** form of [sflow extension switch](#) and **no** form of [sflow extension router](#) commands prevent the addition of extended switch and router information to sFlow sample packets.

## Example

These commands prevent extended switch and router information from being added to sFlow sample packets.

```
switch(config) # no sflow extension switch
switch(config) # no sflow extension router
switch(config) #
```

## Support for VPLS on sFlow

For VPLS forwarded traffic, the sFlow datagram includes the name of the VPLS instance and the ID of the pseudowire where the packet egresses.

Use the following command to add the VPLS extension to capture relevant VPLS information:

```
switch(config)#sflow extension vpls
```

## Enabling sFlow

The **sflow run** command globally enables sFlow on the switch. The **sflow enable** command controls sFlow operation on Ethernet and port channel interfaces when sFlow is globally enabled. The **sflow enable** command has no effect disabling sFlow globally.

### Example

These commands enable sFlow on the switch, then disables sFlow on Ethernet interface 10.

```
switch(config)# sflow run
switch(config)# interface ethernet 10
switch(config-if-Et10)# no sflow enable
switch(config) #
```

## 21.4.3 Egress Sampling for sFlow Interfaces

EOS supports egress sampling for sFlow on Ethernet interfaces, port channels, and subinterfaces on select platforms. Egress sFlow does not support hardware acceleration. Sample processing occurs in EOS.

### Configuring Egress Sampling on sFlow Interfaces

EOS disables Egress sFlow by default. Use the following command to enable egress sFlow for all interfaces:

```
switch(config)# sflow interface egress enable default
```

Override the global egress sFlow configuration by disabling it on a specified interface:

```
switch(config)# interface Ethernet1
switch(config-if-Et1)# no sflow egress enable
```

### Displaying Egress sFlow Configurations

To display information about the Egress sFlow configuration, use the **show sflow interfaces** command.

```
switch# show sflow interfaces
Default ingress sFlow configuration for an interface: Enabled
Default egress sFlow configuration for an interface: Disabled
 sFlow Interface (s):

 Ethernet20/1 - running(Ingress,Egress,Counter)
 Ethernet21/1 - running(Ingress,Counter), inactive(Egress)
 Port-Channel1 - running(Counter), partial(Egress)
 Port-Channel2 - running(Ingress,Egress,Counter)
```

In the output, the parameter, **inactive**, indicates that the interface has been configured for Egress sFlow, but not operational. The parameter, **partial**, displays the Port-Channel inoperational members, but other members are operational.

Adding the parameter, ***detail***, shows active and inactive Port-Channel members.

| Interface     | Member      | Ingress      | Egress   | Counter |
|---------------|-------------|--------------|----------|---------|
| Ethernet20/1  |             | running      | running  | running |
| Ethernet21/1  |             | running      | inactive | running |
| Port-Channel1 |             | unconfigured | partial  | running |
| Port-Channel1 | Ethernet1/1 | unconfigured | inactive | running |
| Port-Channel1 | Ethernet2/1 | unconfigured | running  | running |
| Port-Channel1 | Ethernet3/1 | unconfigured | running  | running |
| Port-Channel2 |             | running      | running  | running |

### Verifying an Egress sFlow Configuration

If the configuration does not send Egress samples to the collector, verify that you have active Egress sFlow interfaces:

```
switch# show sflow interfaces
sFlow Interface (s):

Ethernet1 - running(Egress,Counter)
Ethernet2 - running(Ingress,Counter)
Ethernet3 - running(Ingress,Egress,Counter)
Ethernet4 - running(Ingress,Counter), inactive(Egress)
```

The output, **inactive(Egress)** indicates that an Egress sFlow has been configured, but not operational.

## 21.4.4 sFlow Subinterfaces

The **sflow sample [input | output] subinterface** command configures **ifIndex** values for subinterfaces on input and output ports to be included in the sFlow sample. These values replace the default parent port **ifIndex** value. Enabling this feature changes all sFlow samples generated by the switch from compact to the expanded format.

### Configuring sFlow Subinterface

The following configures subinterfaces on the switch for sampling.

```
switch (config) # sflow run
switch (config-if-Et1) # sflow sample input subinterface
switch (config) # sflow sample output subinterface
```

The following file extract displays the output from a **show sflow detail** command.

```
switch# show sflow detail
...
Status

...
Sample Switch Extension: Yes
Sample Router Extension: Yes
Sample Tunnel IPv4 Egress Extension: No
Sample Input Subinterface: Yes
Sample Output Subinterface: Yes
Port Channel Output Interface Index: portchannel
Sample Encoding Format: expanded
...
```

## Limitations

- Only some hardware platforms support this feature.
- Only L3 subinterfaces and QinQ L3 subinterfaces support the sFlow output subinterface.
- sFlow does not support tunneled packets such as GRE, MPLSoGRE, and IPinIP.

## 21.4.5 sFlow Commands

### Global Configuration Commands

- [sflow destination](#)
- [sflow extension bgp](#)
- [sflow extension router](#)
- [sflow extension switch](#)
- [sflow extension vpls](#)
- [sflow polling-interval](#)
- [sflow run](#)
- [sflow sample](#)
- [sflow sample output interface](#)
- [sflow source](#)
- [sflow source-interface](#)

### Interface Configuration Commands

- [sflow enable](#)

### Privileged EXEC Command

- [clear sflow counters](#)
- [sflow datagram](#)
- [sflow interface](#)

### sFlow Display Commands

- [show sflow](#)
- [show sflow interfaces](#)

## 21.4.5.1 clear sflow counters

The `clear sflow counters` command resets the global sFlow statistics, which includes the number of samples and sample pool. The hardware trigger count is not reset.

The `show sflow` command displays global sFlow statistics.

### Command Mode

Privileged EXEC

### Command Syntax

```
clear sflow counters
```

---

## Example

This command resets the sFlow counters.

```
switch# clear sflow counters
switch#
```

### 21.4.5.2 sflow datagram

The **sflow datagram** command configures the size of the sFlow datagram from 200 to 1500 bytes to help avoid fragmentation of the datagram.

**Note:** EOS supports this feature in software sFlow.

#### Command Mode

Privileged EXEC

#### Command Syntax

```
sflow datagram size maximum bytes
```

#### Parameters

*bytes* - Configure the size of the datagram from 200 to 1500 bytes.

#### Example

Use the following command to configure an sFlow datagram in 1000 bytes:

```
switch(config) # sflow datagram size maximum 1000
```

### 21.4.5.3 sflow destination

The **sflow destination** command specifies an sFlow collector IPv4 or IPv6 address and, optionally, a UDP port (the default is 6343). The switch supports sFlow collector addresses through multiple sFlow destination commands in **running-config**.

The **no sflow destination** and **default sflow destination** commands remove the specified sFlow collector IP address by deleting the corresponding **sflow destination** command from **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
sflow destination dest_addr [UDP_PORT]
no sflow destination dest_addr [UDP_PORT]
default sflow destination dest_addr [UDP_PORT]
```

#### Parameters

- ***dest\_addr*** sflow collector's IP address.

- **UDP\_PORT** sFlow collectors data reception port. Options include:
  - **no parameter** port number **6343** (default).
  - **port\_num** port number. Value ranges from **0** to **65535**.

### Example

This command configures the switch to send sFlow data to the collector located at **2001:0db8::2**; the collector receives the data through UDP port **6100**.

```
switch(config)# sflow destination 2001:0db8::2 6100
switch(config) #
```

### 21.4.5.4 sflow enable

The **sflow enable** command enables sFlow on the configuration mode interface. When globally enabling sFlow using the **sflow run** command, the command enables sFlow on all interfaces by default. Use the **sflow enable** command when **running-config** contains a **no sflow enable** statement for the specified interface.

The **no sflow enable** command disables sFlow on the configuration mode interface. When globally disabled, this command persists in **running-config** but does not affect switch operation.

The **default sflow enable** command removes the corresponding **no sflow enable** command from **running-config** enabling sFlow capability on the interface.

#### Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

#### Command Syntax

```
sflow enable
no sflow enable
default sflow enable
```

#### Examples

- These commands enable sFlow on the switch and disable sFlow on **interface ethernet 12**.

```
switch(config)# sflow run
switch(config)# interface ethernet 12
switch(config-if-Et12)# no sflow enable
switch(config-if-Et12) #
```

- This command removes the **no sflow enable** command for **interface ethernet 12** from **running-config**, enabling sFlow on the interface whenever sFlow is globally enabled.

```
switch(config-if-Et12)# sflow enable
switch(config-if-Et12) #
```

### 21.4.5.5 sflow extension bgp

The **sflow extension bgp** command enables BGP export to sFlow. When enabled, the routing agent will export the BGP routing table and autonomous system path information to the sFlow agent. When sFlow

---

receives a sampled packets whose destination is a BGP route, it will look up the following additional BGP routing information and include it in the sample:

Next hop IP address

- AS numbers
- AS system path to the destination
- Communities
- Local preferences

The **no sflow extension bgp** and **default sflow extension bgp** commands disable BGP export to sFlow by deleting the corresponding **sflow extension bgp** command from **running-config**.

**Note:** A BGP instance must be configured on the switch for BGP sFlow export to function.

### Command Mode

Global Configuration

### Command Syntax

```
sflow extension bgp
no sflow extension bgp
default sflow extension bgp
```

### Guidelines

BGP sFlow export behaves differently on different switch platforms as follows:

- DCS-7500E switches use actual hardware egress port information in sFlow packets. All other platforms use software simulation to determine the egress port.
- On Arad platform switches (DCS-7280E and DCS-7500E), BGP sFlow export works for sample packets with ECMP destination routes unless they exit the switch through a trunk port or subinterface. When a trunk port or subinterface provides the egress port, the sample packet only includes AS path information from the first path of the ECMP route and a BGP next hop of **0**.
- On all other switch platforms, ECMP destination routes includes AS path information from the first path, but identifies the BGP next hop as **0**.
- DCS-7500E switches use actual hardware egress port information in sFlow packets. All other platforms use software simulation to determine the egress port.

### Example

Use the following commands to configure a BGP instance in **AS 50** and enable BGP sFlow export globally.

```
switch(config)# router bgp 50
switch(config-router-bgp)# exit
switch(config)# sflow extension bgp
switch(config) #
```

## 21.4.5.6 sflow extension router

By default, the switch provides extended router information in sFlow packets, including the IP version and address of the next-hop router and source and destination mask lengths.

The **no** version of the **sflow extension router** command prevents this information from being included in sFlow packets.

The **sflow extension router** and **default sflow extension router** commands restore the default behavior by deleting the corresponding **no sflow extension router** command from ***running-config***.

#### Command Mode

Global Configuration

#### Command Syntax

```
sflow extension router
no sflow extension router
default sflow extension router
```

#### Example

This command prevents the switch from including extended router information in sFlow packets.

```
switch(config)# no sflow extension router
switch(config) #
```

### 21.4.5.7 sflow extension switch

By default, the switch provides extended switch information in sFlow packets, including source and destination VLANs and priorities.

The **no** version of the **sflow extension switch** command prevents this information from being included in sFlow packets.

The **sflow extension switch** and **default sflow extension switch** commands restore the default behavior by deleting the corresponding **no sflow extension switch** command from ***running-config***.

#### Command Mode

Global Configuration

#### Command Syntax

```
sflow extension switch
no sflow extension switch
default sflow extension switch
```

#### Example

This command prevents the switch from including extended switch information in sFlow packets.

```
switch(config)# no sflow extension switch
switch(config) #
```

### 21.4.5.8 sflow extension vpls

The **sflow extension vpls** command enables VPLS exporting to sFlow configuration. When enabled, the routing agent exports VPLS information to the sFlow agent.

The **no sflow extension vpls** and **default sflow extension vpls** commands disable VPLS exporting to sFlow by deleting the corresponding **sflow extension vpls** command from ***running-config***.

**Note:** VPLS must be configured on the switch for VPLS sFlow export to operate.

## Command Mode

Global Configuration

### Command Syntax

```
sflow extension vpls
no sflow extension vpls
default sflow extension vpls
```

Use the following command to enable VPLS export to sFlow:

```
switch(config)#sflow extension vpls
```

### 21.4.5.9 sflow interface

The **sflow interface** command enables the configuration of egress sFlow on an interface.

#### Command Mode

EXEC

#### Command Syntax

```
sflow interface
```

#### Examples

- This command enables global egress sFlow for all interfaces.

```
switch# sflow interface egress enable default
```

- This command enables egress sFlow on an interface.

```
switch(config)# interface Ethernet1
switch(config-if-Et1)# sflow egress enable
```

### 21.4.5.10 sflow polling-interval

The **sflow polling-interval** command specifies the counters polling interval. The switch uses this interval to schedule a ports counter data transmissions to the sFlow collector.

The default interval is two seconds.

The **no sflow polling-interval** and **default sflow polling-interval** commands revert the polling interval to the default of two seconds by removing the **sflow polling-interval** command from **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
sflow polling-interval interval_period
no sflow polling-interval
default sflow polling-interval
```

#### Parameters

**interval\_period** polling interval (seconds). Value ranges from **0** to **3600 (60 minutes)**. Default is **2**.

#### Example

This command configures the switch to send sFlow counter data every **10** seconds.

```
switch(config)# sflow polling-interval 10
switch(config) #
```

---

### 21.4.5.11 sflow run

The **sflow run** command globally enables sFlow on the switch. EOS disables the sFlow global setting by default. You cannot enable sFlow on individual interfaces when disabling sFlow globally.

The **sflow enable** interface configuration command controls sFlow operation on individual Ethernet and Port Channel interfaces when enabling sFlow globally. When enabled globally, it enables sFlow on all interfaces by default.

The **no sflow run** and **default sflow run** commands globally disable sFlow on the switch.

#### Command Mode

Global Configuration

#### Command Syntax

```
sflow run
no sflow run
default sflow run
```

#### Examples

- Use this command to enable sFlow on the switch.

```
switch(config)# sflow run
switch(config)#{
```

- Use this command to globally disable sFlow.

```
switch(config)# no sflow run
switch(config)#{
```

---

### 21.4.5.12 sflow sample

The **sflow sample** command sets the packet sampling rate. Packets sample at random intervals to avoid inaccurate sampling of periodic events. The packet sampling rate defines the average number of ingress packets that pass through an interface for every sampled packet. A rate of **16384** corresponds to an average sample of one per **16384** packets. The switch may drop samples if it cannot manage the configured sample rate. Under normal operation, the maximum packet sample rate occurs at one per **16384** packets.

By default, samples include information about the output interface. To remove this information, use the **no sflow sample output interface** command.

Optionally, use the **sflow sample** command to configure packets with information about the traffic class of the sample. sFlow communicates the traffic class by rewriting the DSCP field in the sample packet.

The **no sflow sample** and **default sflow sample** commands reset the packet sampling rate to the default of **1048576** and remove output interface and traffic class information from samples by removing the **sflow sample** command from the configuration.

#### Command Mode

Global Configuration

#### Command Syntax

```
sflow sample sample_rate truncate size 128_512 rewrite dscp vxlan
no sflow sample
```

```
default sflow sample
```

## Parameters

**sample\_rate** - Specifies the size of the packet sample to select a packet. Default sample size is 1048576 packets. Options include the following:

- **recommended\_rate** - An integer between **16384** and **16777215**.
- **rewrite dscp** - Configures sFlow to rewrite the DSCP field of sample packets to indicate the traffic class of the original packet.
- **truncate size** - Sets the sFlow sample truncation size between the range of **128** to **512**. By default, EOS sets the sFlow sample truncate size to **128**.

## Examples

- This command configures the sFlow sampling rate as **65536**, one per **65536** packets).

```
switch(config)# sflow sample 65536
switch(config)#
```

- This command configures the sFlow sampling rate as **256**, one per **256** packets).

```
switch(config)# sflow sample dangerous 256
switch(config)#
```

- This command configures sFlow to include traffic class information in samples.

```
switch(config)# sflow sample rewrite dscp
switch(config)#
```

- Use the following command to truncate the packet bytes to 256.

```
switch(config)# sflow sample truncate 256
```

---

#### **21.4.5.13 sflow sample output interface**

By default, sFlow samples include information about the output interface of the sampled packet. The **no sflow sample output interface** command excludes the information.

##### **Command Mode**

Global Configuration

##### **Command Syntax**

**no sflow sample output interface**

##### **Example**

This command configures sFlow to exclude output interface information in samples.

```
switch(config)# no sflow sample output interface
switch(config)#{
```

#### 21.4.5.14 sflow source

The **sflow source** command specifies the IP address used in the **Agent** address field of the IPv4 or IPv6 sFlow datagram that the switch sends to the collector. This command cannot be used if **running-config** contains an **sflow source-interface** command.

The **no sflow source** and **default sflow source** commands remove the **sflow source** command from **running-config**.

##### Command Mode

Global Configuration

##### Command Syntax

```
sflow source source_addr
no sflow source
default sflow source
```

##### Parameter

**source\_addr** source IP address (dotted decimal notation).

##### Example

This command configures 2001:0db8::2 as the sFlow source address.

```
switch(config)# sflow source 2001:0db8::2
switch(config)#
```

#### 21.4.5.15 sflow source-interface

The **sflow source-interface** command specifies the source IP address set to the IP address of the specified interfaces that the switch sends to the collector. An sFlow packet specifies both the Agent address in the IPv4 or IPv6 sFlow datagram and the source IP address sent to the collector. This command cannot be used if **running-config** contains an **sflow source** command.

The **no sflow source-interface** and **default sflow source-interface** commands remove the **sflow source-interface** command from **running-config**.

##### Command Mode

Global Configuration

##### Command Syntax

```
sflow source-interface INT_NAME
no sflow source-interface
default sflow source-interface
```

##### Parameters

**INT\_NAME** Interface type and number. Options include:

- **interface ethernet e\_num** Ethernet interface specified by **e\_num**.
- **interface loopback l\_num** Loopback interface specified by **l\_num**.
- **interface management m\_num** Management interface specified by **m\_num**.

- 
- **interface port-channel *p\_num*** Port-Channel Interface specified by *p\_num*.
  - **interface vlan *v\_num*** VLAN interface specified by *v\_num*.

### Example

This command configures the sFlow source address as the IP address assigned to the **loopback 0** interface.

```
switch(config)# sflow source-interface loopback 0
switch(config)#{
```

### 21.4.5.16 show sflow

The **show sflow** command displays configured sFlow parameters, operational status, and statistics.

The **show sflow interfaces** command displays the interfaces where sFlow is enabled.

#### Command Mode

EXEC

#### Command Syntax

```
show sflow [detail]
```

#### Parameter

**detail** adds hardware sampling status and number of discarded samples to the information displayed.

#### Examples

- This command displays the base sFlow information.

```
switch# show sflow
! Displaying counters that may be stale
sFlow Configuration

Destinations: None (default)
Source(s):
 0.0.0.0 (default) (VRF: default)

#### 21.4.5.17 show sflow interfaces

The **show sflow interfaces** command displays the interfaces with sFlow enabled.

The **show sflow** command displays configured sFlow parameters, operational status, and statistics.

##### Command Mode

EXEC

##### Command Syntax

**show sflow interfaces**

##### Parameters

***detail***

## Examples

- This command displays the `show sflow interface` message when globally disabling sFlow.

```
switch# show sflow interfaces
sFlow Interface (s):

sFlow is not running
```

- This command displays the `show sflow interface` message when enabling sFlow globally and enabling sFlow on all interfaces.

```
switch(config)# sflow run
switch(config)# show sflow interfaces
Default sFlow configuration for an interface: Disable
sFlow Interface (s):

Ethernet1 running(Counter)
Ethernet2 running(Counter)
Ethernet3 running(Flow,Counter)
Ethernet4 running(Flow,Counter)
Ethernet5 running(Flow,Counter)
```

- To review active and inactive sFlow interfaces, use the `sflow interfaces detail` command:

| Interface      | Member      | Ingress      | Egress   | Counter |
|----------------|-------------|--------------|----------|---------|
| Ethernet20/1   |             | running      | running  | running |
| Ethernet21/1   |             | running      | inactive | running |
| Port-Channel1  |             | unconfigured | partial  | running |
| Port-Channel11 | Ethernet1/1 | unconfigured | inactive | running |
| Port-Channel11 | Ethernet2/1 | unconfigured | running  | running |
| Port-Channel11 | Ethernet3/1 | unconfigured | running  | running |
| Port-Channel2  |             | running      | running  | running |

## 21.5 SNMP

This chapter describes the Arista switch SNMP agent and contains these sections:

- [SNMP Introduction](#)
- [SNMP Conceptual Overview](#)
- [Configuring SNMP](#)
- [SNMP Commands](#)

### 21.5.1 SNMP Introduction

Arista Networks switches support many standard SNMP MIBs, making it easier to integrate these platforms into existing network management infrastructures.

With only a few configurations, many public domain and commercially available network management tools can quickly manage Arista switches out of the box. Support of SNMP V2 groups and views and V3 security allow network managers to tune switch monitoring to match the administration policy of the IT organization.

### 21.5.2 SNMP Conceptual Overview

Simple Network Management Protocol (SNMP) is a protocol that provides a standardized framework and a common language to monitor and manage network devices.

### 21.5.2.1 SNMP Structure

The SNMP framework has three parts:

- **SNMP manager:** The SNMP manager controls and monitors network host activities and is typically part of a Network Management System (NMS).
- **SNMP agent:** The SNMP agent is the managed device component that manages and reports device information to the manager.
- **Management Information Base (MIB):** The MIB stores network management information.

The agent and MIB reside on the switch. Enabling the SNMP agent requires the definition of the manager-agent relationship. The agent contains MIB variables whose values the manager can request or change. The agent gathers data from the MIB and responds to requests for information. For a list of supported MIBs, refer to the release notes for the specific EOS version.

This chapter discusses enabling the SNMP agent on an Arista switch and controlling notification transmissions from the agent. Information on using SNMP management systems is available in the appropriate documentation for the corresponding NMS application.

### 21.5.2.2 SNMP Notifications

SNMP notifications are messages, sent by the agent, informing of an event or a network condition. A **trap** is an unsolicited notification. An **inform** (or inform request) is a trap that includes a request for a confirmation that the message is received. Events that a notification can indicate include improper user authentication, restart, and connection losses.

For a list of supported traps, refer to the release notes for the specific EOS version.

### 21.5.2.3 SNMP Versions

Arista switches support the following SNMP versions:

- **SNMPv1:** The Simple Network Management Protocol, defined in *RFC 1157*. Security is based on community strings.
- **SNMPv2c:** Community-string based Administrative Framework for SNMPv2, defined in *RFC 1901*, *RFC 1905*, and *RFC 1906*. Security is based on SNMPv1.
- **SNMPv3:** Version 3, as defined in *RFC 2273* to *RFC 2275*.

### 21.5.2.4 SNMP Authentication and Encryption Methods

The following are the SNMP stronger Authentication and Encryption methods:

- **Authentication**

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

- **Encryption**

- AES
- DES

- AES-192
- AES-256

**Note:** Use the following minimums when using the stronger SNMPv3 encryption algorithm to avoid any interoperability issues.

- When using AES-192 for encryption/privacy, use a minimum of SHA-224 for authentication.
- When using AES-256 for encryption/privacy, use a minimum of SHA-256 for authentication.

## 21.5.3 Configuring SNMP

This section describes the steps that configure the switch SNMP agent to communicate with an SNMP manager, including the following:

- [Enabling and Disabling SNMP](#)
- [Enabling SNMP in a VRF](#)
- [Configuring Community Access Control](#)
- [Configuring SNMP Parameters](#)
- [Configuring the Agent to Send Notifications](#)
- [Extending the SNMP Agent Through Runtime Scripts](#)
- [SNMP IP Address ACL Support](#)

### 21.5.3.1 Enabling and Disabling SNMP

SNMP is enabled globally by issuing any [snmp-server community](#) or [snmp-server user](#) command. The [no snmp-server](#) command disables SNMP agent operation by removing all non-default [snmp-server](#) commands from ***running-config***.

### 21.5.3.2 Enabling SNMP in a VRF

By default, SNMP is enabled only in the **default** VRF. The switch can only send SNMP traps and informs if the host that has been configured to receive them is accessible through an interface in a VRF in which SNMP has been enabled.

To enable or disable SNMP in a VRF, use the [snmp-server vrf](#) command.

### 21.5.3.3 Configuring Community Access Control

SNMP community strings serve as passwords that permit an SNMP manager to access the agent on the switch. A Network Management System (NMS) can access the switch only if its community string matches at least one of the switch's community strings.

The [snmp-server community](#) command configures the community string.

The following command adds the community string **ab\_1** to provide read-only access to the switch agent.

```
switch(config)# snmp-server community ab_1 ro
switch(config)#
```

Community statements can reference views to limit MIB objects that are available to a manager. A view is a community string object that specifies a subset of MIB objects. The `snmp-server view` command configures the community string.

## Examples

- These commands create a view that includes all objects in the `system` group except for those in `system.2`.

```
switch(config)# snmp-server view sys-view system include
switch(config)# snmp-server view sys-view system.2 exclude
switch(config)#

```

- This command adds the community string `lab_1` to provide read-only access to the switch agent for the previously defined view.

```
switch(config)# snmp-server community lab_1 view sys-view
switch(config)#

```

### 21.5.3.4 Configuring SNMP Parameters

This section describes these SNMP parameter configuration tasks:

- [Configuring the Engine ID](#)
- [Configuring the Group](#)
- [Configuring the User](#)
- [Configuring the Host](#)
- [Enabling Link Trap Generation](#)
- [Specifying the Source Interface](#)
- [Configuring the Chassis-id String](#)
- [Configuring the Contact String](#)
- [Configuring the Location String](#)

#### 21.5.3.4.1 Configuring the Engine ID

The `snmp-server engineID remote` command configures the name of a Simple Network Management Protocol (SNMP) engine located on a remote device. Use the `snmp-server engineID local` command for the local engine.

A remote agent's engine ID must be configured before remote users for that agent are configured. User authentication and privacy digests are derived from the engine ID and user passwords. The configuration command fails if the remote engine ID is not configured first.

 **Note:** When the remote engine ID is changed, all user passwords associated with the engine must be reconfigured.

### Example

This command configures **DC945798CAB4** as the name of the remote SNMP engine located at **12.23.104.25**, UDP **port 162**

```
switch(config)# snmp-server engineID remote 10.23.104.25 udp-port DC945798CA
switch(config)#

```

#### 21.5.3.4.2 Configuring the Group

An SNMP group grants specific levels of SNMP access to group users. The [snmp-server group](#) command configures a new SNMP group.

This command configures **normal\_one** as an SNMPv3 group (authentication and encryption) that provides access to the **all-items** read view.

```
switch(config)# snmp-server group normal_one v3 priv read all-items
switch(config) #
```

#### 21.5.3.4.3 Configuring the User

Members of SNMP groups are called **users**. The [snmp-server user](#) command allows a new user to be added an SNMP group and configures that user's parameters. Remote users are configured by specifying the IP address or port number that accesses the user's SNMP agent.

##### Examples

- This command configures the local SNMPv3 user **tech-1** as a member of the SNMP group **tech-sup**.

```
switch(config)# snmp-server user tech-1 tech-sup v3
switch(config) #
```

- This command configures the remote SNMPv3 user **tech-2** as a member of the SNMP group **tech-sup**. The remote user is on the agent located at **13.1.1.4**.

```
switch(config)# snmp-server user tech-2 tech-sup remote 13.1.1.4 v3
switch(config) #
```

#### 21.5.3.4.4 Configuring the Host

The [snmp-server host](#) command configures an SNMP host (to which SNMP traps will be sent). The [snmp-server host](#) command sets the community string if it was not previously configured.

##### Example

This command adds a v2c inform notification recipient at **12.15.2.3** using the community string **comm-1**.

```
switch(config)# snmp-server host 12.15.2.3 informs version 2c comm-1
switch(config) #
```

#### 21.5.3.4.5 Enabling Link Trap Generation

The [snmp trap link-change](#) command enables SNMP link trap generation on the configuration mode interface. SNMP link trap generation is enabled by default. If SNMP link trap generation was previously disabled, this command removes the corresponding **no snmp link-status** statement from the configuration. The [show snmp notification](#) command displays the SNMP link trap generation information.

##### Example

This command disables SNMP link trap generation on the **interface ethernet 5**.

```
switch(config-if-Et5)# no snmp trap link-change
```

```
switch(config-if-Et5) #
```

#### 21.5.3.4.6 Specifying the Source Interface

The [snmp-server local-interface](#) command specifies the interface from where an SNMP trap originates. The [show snmp local-interface](#) command displays the interface of the IP address for SNMP traps.

##### Example

This command configures the ***ethernet 1*** interface as the source of SNMP traps and informs.

```
switch(config)# snmp-server local-interface ethernet 1
switch(config) #
```

#### 21.5.3.4.7 Configuring the Chassis-id String

The chassis ID string is typically set to the serial number of the switch. The SNMP manager uses this string to associate all data retrieved from the switch with a unique identifying label. Under normal operating conditions, editing the chassis ID string contents is unnecessary.

The [snmp-server chassis-id](#) command configures the chassis ID string. The default chassis ID string is the serial number of the switch. The [show snmp](#) command displays the chassis ID.

##### Example

This command configures ***xyz-1234*** as the chassis-ID string, then displays the result.

```
switch(config)# snmp-server chassis-id xyz-1234
switch(config)# show snmp
Chassis: xyz-1234 <---chassis ID
8 SNMP packets input
 0 Bad SNMP version errors
 0 Unknown community name
 0 Illegal operation for community name supplied
 0 Encoding errors
 8 Number of requested variables
 0 Number of altered variables
 4 Get-request PDUs
 4 Get-next PDUs
 0 Set-request PDUs
21 SNMP packets output
 0 Too big errors
 0 No such name errors
 0 Bad value errors
 0 General errors
 8 Response PDUs
 0 Trap PDUs
SNMP logging: enabled
 Logging to taccon.162
SNMP agent enabled
switch(config) #
```

#### 21.5.3.4.8 Configuring the Contact String

The SNMP contact string is information text that typically displays the name of a person or organization associated with the SNMP agent.

The [snmp-server contact](#) command configures the system contact string. The contact string is displayed by the [show snmp](#) and [show snmp v2-mib contact](#) commands.

---

### Example

These commands configure **Bonnie H at 3-1470** as the contact string.

```
switch(config) # snmp-server contact Bonnie H at 3-1470
switch(config) #
```

#### 21.5.3.4.9 Configuring the Location String

The location string typically provides information about the physical location of the SNMP agent. The [snmp-server location](#) command configures the system location string. By default, the system location string is not set.

### Example

These commands configure **lab-25** as the location string.

```
switch(config) # snmp-server location lab_25
switch(config) # show snmp v2-mib location
Location: lab_25
switch(config) #
```

#### 21.5.3.5 Configuring the Agent to Send Notifications

The following tasks are mandatory when setting up the SNMP agent to send notifications:

1. Configure the remote engine ID.
2. Configure the group.
3. Configure the user.
4. Configure the host.
5. Enable link trap generation on the interfaces.

[Configuring SNMP Parameters](#) describes each of these tasks.

#### 21.5.3.6 Extending the SNMP Agent Through Runtime Scripts

The switch supports the execution of user supplied scripts to service portions of the OID space.

Scripts run under one of two operational modes:

- **Normal mode** scripts run over an indefinite period to process subsequent objects after the initial request. Maintaining an executing script avoids startup and connection delay each time an object requires processing.
- **One-shot mode** scripts process a single object, then terminate execution; requires the **one-shot** keyword.

Startup and data collection overhead is required for each request. In both modes, the SNMP server is blocked from serving other requests when waiting for script responses.

The [snmp-server extension](#) command configures the execution of user-supplied scripts to service portions of the OID space. Use the **one-shot** keyword to specify one-shot execution.

### Examples

- This command specifies the file ***normal-example.sh***, located in flash as the script file that services the specified OID space in normal mode.

```
switch(config)# snmp-server extension .1.3.6.1.4.1.8072.2 flash:normal-example.sh
switch(config)#

```

- Contents of the script file:

```
#!/bin/bash
while read cmd; do
 case $cmd in
 PING)
 printf "PONG\n"
 ;;
 get)
 read oid
 printf "$oid\n"
 printf "integer\n"
 printf "42\n"
 printf "NONE\n"
 ;;
 esac
 done

```

- Testing the script:

```
switch(config)# show snmp mib get .1.3.6.1.4.1.8072.2
NET-SNMP-EXAMPLES-MIB::netSnmpExamples = INTEGER: 42
switch(config)#

```

- This command specifies the file ***one-shot-example.sh***, located in flash as the script file that services the specified OID space in one-shot mode, executing once and then exiting.

```
switch(config)# snmp-server extension .1.3.6.1.4.1.8072.2 flash:one-shot-example.sh one-shot
switch(config)#

```

- Contents of the script file:

```
#!/bin/bash
oid="$2"
printf "$oid\n"
printf "integer\n"
printf "42\n"
```

- Testing the script:

```
switch(config)# show snmp mib get .1.3.6.1.4.1.8072.2 NET-SNMP-EXAMPLES-MIB::netSnmpExamples =
INTEGER: 42

```

### 21.5.3.6.1 Normal Script Behavior

The first time the SNMP server requires a script result, it launches it with no arguments. The server communicates with the script through **stdin/stdout**. Before each request, the script is sent the string **PING\n** on **stdin**. The expected response from the script is printing **PONG\n** to **stdout**.

#### GET and GETNEXT Requests

For **GET** and **GETNEXT** requests, the script is passed two lines on **stdin**, the command (**get** or **getnext**) and the requested OID. The expected response from the script is the printing of three lines to **stdout**: the OID for the result varbind, the **TYPE**, and the **VALUE** itself.

[Table 139: Extension Script Type and Encoding](#) lists legal TYPE values and resulting VALUE encodings. If the command does not return an appropriate varbind, it should print **NONE\n** to **stdout** and continue running; this results in an SNMP **noSuchName** error or a **noSuchInstance** exception.

---

**Table 139: Extension Script Type and Encoding**

| Type string | SNMP type   | Encoding for script |
|-------------|-------------|---------------------|
| integer     | Integer32   | integer             |
| unsigned    | Unsigned32  | integer             |
| gauge       | Gauge32     | integer             |
| counter     | Counter32   | integer             |
| counter64   | Counter64   | integer             |
| timetick    | TimeTicks   | integer             |
| ipaddress   | IpAddress   | a.b.c.d             |
| objectid    | ObjectID    | 1.3.6.1.42.99.2468  |
| octet       | OctetString | hexadecimal string  |
| opaque      | Opaque      | hexadecimal string  |
| string      | OctetString | ascii string        |

## SET Requests

For **SET** requests, script is passed three lines on stdin: the command (set), and the requested OID, and the **TYPE** and **VALUE**, both on the same line. If the assignment is successful, the expected script response is to print **DONE\n** to **stdout**. Indicated errors by writing one of the error strings described in **Set Request Error Strings**. In each case, the command should continue running.

**Table 140: Set Request Error Strings**

|                     |                      |                |
|---------------------|----------------------|----------------|
| authorization-error | no-access            | too-big        |
| bad-value           | no-creation          | undo-failed    |
| commit-failed       | no-such-name         | wrong-type     |
| gen-error           | not-writable         | wrong-length   |
| inconsistent-name   | read-only            | wrong-encoding |
| inconsistent-value  | resource-unavailable | wrong-value    |

### 21.5.3.6.2 One-Shot Script Behavior

The command should exit after it finishes processing a single object.

## GET and GETNEXT

For each **GET** or **GETNEXT** request, the script is invoked once for each OID in the space that it serves. It receives two arguments: -g for **GET** or -n for **GETNEXT**, and the requested OID.

The expected script response is the response varbind as three separate lines printed to **stdout**: the result OID, the type, and the value.

If the command does not return an appropriate varbind, then the script should exit without producing any output. This results in an SNMP **noSuchName** error, or a **noSuchInstance** exception.

Possible reasons that a command would not return an appropriate varbind includes:

- The specified OID didn't correspond to a valid instance for a **GET** request.

- There were no following instances for a **GETNEXT**.

## SET

A SET request results in the command being called with the arguments: -s, **OID**, **TYPE** and **VALUE**, where **TYPE** is a listed token. [Normal Script Behavior](#) indicates the type of the value passed as the third parameter.

When the assignment is successful, the script exits without producing any output. Errors are indicated by writing just the error name ([Normal Script Behavior](#)); the agent generates the appropriate error response.

### 21.5.3.7 SNMP IP Address ACL Support

SNMP IP address ACL support provides the ability to add access-lists to limit the source addresses that can be used to query the SNMP server. The access-lists are reachable on the switch through the access SNMP data (**port 161**). The access-lists contain standard **permit** and **deny** commands.

#### 21.5.3.7.1 Configuration

Use the following command to add SNMP IP address ACL support:

```
[no | default] snmp-server [[ipv4 access-list /P4_ACL] | [ipv6 access-list /P6_ACL]][vrf VRF]
```

When the **VRF** is not specified, **default** is assumed.

#### 21.5.3.7.2 Show Commands

Use the **show snmp ipv4 access-list summary** command to display an abbreviated output of an IPv4 access-list.

##### Example

```
switch# show snmp ipv4 access-list summary
IPv4 ACL Permit169
 Total rules configured: 2
 Configured on VRFs: red VRF

 IPv4 ACL Permit168
 Total rules configured: 2
 Configured on VRFs: default VRF
 Active on VRFs: default VRF
```

Use the **show snmp ipv4 access-list detail** command to display a detailed output of an IPv4 access-list.

##### Example

```
switch# show snmp ipv4 access-list detail
IP Access List Permit169
10 permit ip 192.169.199.0/24 any [match 7 packets, 0:19:56 ago]
20 deny ip any any [match 13 packets, 0:03:56 ago]
Total rules configured: 2
Configured on VRFs: red VRF

IP Access List Permit168
10 permit ip 192.168.199.0/24 any [match 7 packets, 0:27:00 ago]
20 deny ip any any [match 13 packets, 0:04:30 ago]
Total rules configured: 2
Configured on VRFs: default VRF
Active on VRFs: default VRF
```

---

Use the **show snmp ipv4 access-list IPv4ACL** command to display a configured access-list. In this example, the configured access-list is **Permit169**.

### Example

```
switch# show snmp ipv4 access-list Permit169
IP Access List Permit169
10 permit ip 192.169.199.0/24 any [match 7 packets, 0:20:12 ago]
20 deny ip any any [match 13 packets, 0:04:12 ago]
Total rules configured: 2
Configured on VRFs: red VRF
```

Use the **show snmp ipv4 access-list summary** command to display a summary of an active access-list.

### Example

```
switch# show snmp ipv4 access-list summary
! Same ACL configured in multiple VRFs. Both VRFs are listed in both the configured
! and the active sessions
IPv4 ACL Permit169
Total rules configured: 2
Configured on VRFs: default VRF
 red VRF
Active on VRFs: default VRF
 red VRF
```

Use the **show snmp ip access-list summary** command to display a short output of the active access-lists.

### Example

```
switch# show snmp ip access-list summary
IPv4 ACL Permit169
Total rules configured: 2
Configured on VRFs: default VRF
 red VRF
Active on VRFs: default VRF
```

## 21.5.4 SNMP Commands

### Global Configuration Commands

- [no snmp-server](#)
- [snmp-server chassis-id](#)
- [snmp-server community](#)
- [snmp-server contact](#)
- [snmp-server enable traps](#)
- [snmp-server engineID local](#)
- [snmp-server engineID remote](#)
- [snmp-server extension](#)
- [snmp-server group](#)
- [snmp-server host](#)
- [snmp-server local-interface](#)
- [snmp-server location](#)
- [snmp-server qosmib counter-interval](#)
- [snmp-server user](#)
- [snmp-server view](#)
- [snmp-server vrf](#)

### Interface Configuration Commands

- [snmp trap link-change](#)

### Display Commands

- [show snmp](#)
- [show snmp community](#)
- [show snmp engineID](#)
- [show snmp group](#)
- [show snmp local-interface](#)
- [show snmp mib](#)
- [show snmp notification](#)
- [show snmp notification | grep bridge](#)
- [show snmp notification host](#)
- [show snmp user](#)
- [show snmp v2-mib chassis](#)
- [show snmp v2-mib contact](#)
- [show snmp v2-mib location](#)
- [show snmp view](#)

---

#### 21.5.4.1 no snmp-server

The **no snmp-server** and **default snmp-server** commands disable Simple Network Management Protocol (SNMP) agent operation by removing all **snmp-server** commands from **running-config**.

SNMP is enabled with any [snmp-server community](#) or [snmp-server user](#) command.

#### Command Mode

Global Configuration

#### Command Syntax

```
no snmp-server
default snmp-server
```

#### Example

This command disables SNMP agent operation on the switch.

```
switch(config)# no snmp-server
switch(config) #
```

### 21.5.4.2 show snmp

The **show snmp** command displays SNMP information including the SNMP counter status and the chassis ID string.

#### Command Mode

EXEC

#### Command Syntax

**show snmp**

#### Example

This command displays SNMP counter status, the chassis ID, the previously configured location string, logging status and destination, and the VRFs in which the SNMP agent is operating.

```
switch> show snmp
Chassis: JFL08320162
Location: 5470ga.dc
2329135 SNMP packets input
 0 Bad SNMP version errors
 0 Unknown community name
 0 Illegal operation for community name supplied
 0 Encoding errors
 38132599 Number of requested variables
 0 Number of altered variables
 563934 Get-request PDUs
 148236 Get-next PDUs
 0 Set-request PDUs
2329437 SNMP packets output
 0 Too big errors
 0 No such name errors
 0 Bad value errors
 0 General errors
 2329135 Response PDUs
 0 Trap PDUs
SNMP logging: enabled
 Logging to 172.22.22.20.162
SNMP agent configured in VRFs: default
SNMP agent enabled in default VRF switch>
```

---

#### 21.5.4.3 show snmp community

The **show snmp community** command displays the Simple Network Management Protocol (SNMP) community access strings configured by the [snmp-server community](#) command.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp community
```

##### Example

This command displays the list of community access strings configured on the switch.

```
switch> show snmp community
Community name: public switch>
```

#### 21.5.4.4 show snmp engineID

The **show snmp engineID** command displays the local SNMP engine information configured on the switch.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp engineID
```

##### Example

This command displays the ID of the local SNMP engine.

```
switch> show snmp engineid
Local SNMP EngineID: f5717f001c730436d700 switch>
```

---

## 21.5.4.5 show snmp group

The **show snmp group** command shows the names of configured SNMP groups along with the security model, and view status of each group.

### Command Mode

EXEC

### Command Syntax

**show snmp group [GROUP\_LIST]**

### Parameters

**GROUP\_LIST** the name of the group.

- ***no parameter*** displays information about all groups.
- ***group\_name*** the name of the group.

### Field Descriptions

- **groupname** name of the SNMP group.
- **security model** security model used by the group: **v1**, **v2c**, or**v3**.
- **readview** string identifying the group's read view. Refer to the [show snmp view](#) command.
- **writeview** string identifying the group's write view.
- **notifyview** string identifying the group's notify view. This command displays the groups configured on the switch.

### Example

```
switch> show snmp group
groupname : normal security model:v3 priv
readview : all writeview: <no writeview specified>
notifyview: <no notifyview specified>
switch>
```

#### 21.5.4.6 show snmp local-interface

The **show snmp local-interface** command displays the interface whose IP address is the source address for SNMP traps.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp local-interface
```

##### Example

This command displays the source interface for the SNMP notifications.

```
switch> show snmp local-interface
SNMP source interface: Ethernet1 switch>
```

---

#### 21.5.4.7 show snmp mib

The **show snmp mib** command displays values associated with specified MIB object identifiers (OIDs) that are registered on the switch.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp mib OBJECTS
```

##### Parameters

**OBJECTS** object identifiers for which the command returns data. Options include:

- **get** *oid\_1 [oid\_2 ... oid\_x]* values associated with each listed OID.
- **get-next** *oid\_1 [oid\_2 ... oid\_x]* values associated with subsequent OIDs relative to listed OIDs.
- **table** *oid* table associated with specified OID.
- **translate** *oid* object name associated with specified OID.
- **walk** *oid* objects below the specified subtree.

##### Examples

- This command uses the get option to retrieve information about the **sysORID.1 OID**.

```
switch# show snmp mib get sysORID.1
SNMPv2-MIB::sysORID[1] = OID: TCP-MIB::tcpMIB
```

- This command uses the get-next option to retrieve information about the OID that is after **sysORID.8**.

```
switch# show snmp mib get-next sysORID.8
SNMPv2-MIB::sysORDescr[1] = STRING: The MIB module for managing TCP
implementations
```

#### 21.5.4.8 show snmp notification

The **show snmp notification** command displays the SNMP trap generation information.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp notification
```

##### Example

This command displays the SNMP traps configured on the switch.

| Type                   | Name                            | Enabled       |
|------------------------|---------------------------------|---------------|
| entity                 | entConfigChange                 | Yes (default) |
| entity                 | entStateOperDisabled            | Yes (default) |
| entity                 | entStateOperEnabled             | Yes (default) |
| lldp                   | lldpRemTablesChange             | Yes (default) |
| msdpBackwardTransition | msdpBackwardTransition          | Yes           |
| msdpEstablished        | msdpEstablished                 | Yes           |
| snmp                   | linkDown                        | Yes           |
| snmp                   | linkUp                          | Yes           |
| snmpConfigManEvent     | aristaConfigManEvent            | Yes (default) |
| switchover             | aristaRedundancySwitchOverNotif | Yes           |
| test                   | aristaTestNotification          | Yes switch>   |

---

#### 21.5.4.9 show snmp notification host

The **show snmp notification host** command displays information for Simple Network Management Protocol notification. Details include IP address and port number of the Network Management System, notification type, and SNMP version.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp notification host
```

##### Field Descriptions

- **Notification host** - Displays the IP address of the host.
- **udp-port** - Displays the UDP port number.
- **type** - Displays the notification type.
- **refresh** - Displays True if DNS refresh configured and False if not.
- **type** - Displays the notification type.
- **user** - Displays the user access type.
- **security model** - Displays the SNMP version used.
- **traps** - Displays the details of the notification.

##### Example

This command displays the hosts configured on the switch.

```
switch# show snmp notification host
Notification host: 172.22.22.20 udp-port: 162 type: trap refresh: True
user: public security model: v2c switch#
```

#### 21.5.4.10 show snmp notification | grep bridge

Use the `show snmp notification | grep bridge` command to display the enabled or disabled status of each trap type.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp notification | grep bridge
```

##### Example

```
switch(config)# show snmp notification | grep bridge
bridge arista-mac-age Yes
bridge arista-mac-learn No
bridge arista-mac-move No (aristaMacMove default disabled)
```

---

#### 21.5.4.11 show snmp user

The **show snmp user** command shows information about Simple Network Management Protocol (SNMP) users. Information that the command displays about each user includes their SNMP version, the engine ID of the host where they reside, and security information

##### Command Mode

EXEC

##### Command Syntax

**show snmp user [USER\_LIST]**

##### Parameters

**USER\_LIST** the name of the group.

- **no parameter** displays information about all users.
- **user\_name** specifies name of displayed user.

##### Example

This command displays information about the users configured on the switch.

```
switch> show snmp user
User name: test
Security model: v3
Engine ID: f5717f001c73010e0900
Authentication protocol: SHA
Privacy protocol: AES-128
Group name: normal switch>
```

#### 21.5.4.12 show snmp v2-mib chassis

The **show snmp v2-mib chassis** command displays the Simple Network Management Protocol (SNMP) server serial number or the chassis ID string configured by the [snmp-server chassis-id](#) command.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp v2-mib chassis
```

##### Example

This command displays the chassis ID string.

```
switch> show snmp v2-mib chassis
Chassis: JFL08320162 switch>
```

---

#### **21.5.4.13 show snmp v2-mib contact**

The **show snmp v2-mib contact** command displays the Simple Network Management Protocol (SNMP) system contact string configured by the [snmp-server contact](#) command. The command has no effect if a contact string was not previously configured.

##### **Command Mode**

EXEC

##### **Command Syntax**

```
show snmp v2-mib contact
```

##### **Example**

This command displays the contact string contents.

```
switch> show snmp v2-mib contact
Contact: John Smith switch>
```

#### 21.5.4.14 show snmp v2-mib location

The `show snmp v2-mib location` command displays the Simple Network Management Protocol (SNMP) system location string. The [snmp-server location](#) command configures system location details. The command has no effect if a location string was not previously configured.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp v2-mib location
```

##### Example

This command displays the location string contents.

```
switch> show snmp v2-mib location
Location: santa clara switch>
```

#### 21.5.4.15 show snmp view

The `show snmp view` command displays the information of a Simple Network Management Protocol configuration and the associated MIB. SNMP views are configured with the [snmp-server view](#) command.

##### Command Mode

EXEC

##### Command Syntax

```
show snmp view [VIEW_LIST]
```

##### Parameters

**VIEW\_LIST** the name of the view.

- **no parameter** displays information about all views.
- **view\_name** the name of the view.

##### Field Descriptions

- **First column** view name.
- **Second column** name of the MIB object or family.
- **Third column** inclusion level of the specified family within the view.

##### Example

These commands configure an SNMP view, then displays that view.

```
switch(config)# snmp-server view sys-view system include
switch(config)# snmp-server view sys-view system.2 exclude
switch(config)# show snmp view
sys-view system - included
sys-view system.2 - excluded
```

---

#### 21.5.4.16 snmp trap link-change

The **snmp trap link-change** command enables Simple Network Management Protocol (SNMP) link-status trap generation on the configuration mode interface. The generation of link-status traps is enabled by default. If SNMP link-trap generation was previously disabled, this command removes the corresponding **no snmp link-status** statement from the configuration to re-enable link-trap generation.

The **no snmp trap link-change** command disables SNMP link trap generation on the configuration mode interface.

The **snmp trap link-change** and **default snmp trap link-change** commands restore the default behavior by removing the **no snmp trap link-change** command from *running-config*.

#### Command Mode

Interface-Ethernet Configuration Interface-Loopback Configuration Interface-Management Configuration  
Interface-Port-channel Configuration Interface-VLAN Configuration Interface-VXLAN Configuration

#### Command Syntax

```
snmp trap link-change
no snmp trap link-change
default snmp trap link-change
```

#### Guidelines

The switch can only send SNMP traps and informs if the host that has been configured to receive them is accessible through an interface in a VRF in which SNMP has been enabled. SNMP is enabled by default only in the **default** VRF. Enable or disable SNMP in a VRF with the [snmp-server vrf](#) command.

#### Example

This command disables SNMP link trap generation on the **interface ethernet 5**.

```
switch(config-if-Et5)# no snmp trap link-change
switch(config-if-Et5)#

```

### 21.5.4.17 snmp-server chassis-id

The **snmp-server chassis-id** command configures the chassis ID string. The default chassis ID string is the serial number of the switch. The **show snmp** command displays the chassis ID.

The **no snmp-server chassis-id** and **default snmp-server chassis-id** commands restore the default chassis ID string by removing the **snmp-server chassis-id** command from the configuration.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server chassis-id id_text
no snmp-server chassis-id
default snmp-server chassis-id
```

#### Parameters

*id\_text* chassis ID string

#### Example

These commands configure **xyz-1234** as the chassis-id string, then display the result.

```
switch(config)# snmp-server chassis-id xyz-1234
switch(config)# show snmp
Chassis: xyz-1234<---chassis ID
8 SNMP packets input
 0 Bad SNMP version errors
 0 Unknown community name
 0 Illegal operation for community name supplied
 0 Encoding errors
 8 Number of requested variables
 0 Number of altered variables
 4 Get-request PDUs
 4 Get-next PDUs
 0 Set-request PDUs
21 SNMP packets output
 0 Too big errors
 0 No such name errors
 0 Bad value errors
 0 General errors
 8 Response PDUs
 0 Trap PDUs
SNMP logging: enabled
 Logging to taccon.162
SNMP agent enabled
switch(config)#

```

---

#### 21.5.4.18 snmp-server community

The **snmp-server community** command configures the community string. SNMP community strings serve as passwords that permit an SNMP manager to access the agent on the switch. The Network Management System (NMS) must define a community string that matches at least one of the switch community strings to access the switch.

The **no snmp-server community** and **default snmp-server community** commands remove the community access string from the configuration.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server community string_text [MIB_VIEW][ACCESS][ACL_NAMES]
no snmp-server community string_text
default snmp-server community string_text
```

#### Parameters

- **string\_text** community access string.
- **MIB\_VIEW** community access availability. Options include:
  - **no parameter** community string allows access to all objects.
  - **view view\_name** community string allows access only to objects in the **view\_name** view.
- **ACCESS** community access availability. Options include:
  - **no parameter** read-only access (default setting).
  - **ro** read-only access.
  - **rw** read-write access.
- **ACL\_NAMES** community access availability. Options include:
  - **no parameter** community string allows access to all objects.
  - **list\_v4** IPv4 ACL list.
  - **ipv6 list\_v6** IPv6 ACL list.
  - **ipv6 list\_v6 list\_v4** IPv4 and IPv6 ACL list.

#### Example

This command adds the community string **lab\_1** to provide read-only access to the switch agent.

```
switch(config)# snmp-server community lab_1 ro
switch(config)#
```

### 21.5.4.19 snmp-server contact

The **snmp-server contact** command configures the system contact string. The contact is displayed by the [show snmp](#) and [show snmp v2-mib contact](#) commands.

The **no snmp-server contact** and **default snmp-server contact** commands remove the **snmp-server contact** command from the *running-config*.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server contact contact_string
no snmp-server contact
default snmp-server contact
```

#### Parameters

***contact\_string*** system contact string.

#### Example

These commands configure *Bonnie H* as the contact string, then display the result.

```
switch(config)# snmp-server contact Bonnie H
switch(config)# show snmp
Chassis: xyz-1234
Contact: Bonnie H.
8 SNMP packets input
 0 Bad SNMP version errors
 0 Unknown community name
 0 Illegal operation for community name supplied
 0 Encoding errors
 8 Number of requested variables
 0 Number of altered variables
 4 Get-request PDUs
 4 Get-next PDUs
 0 Set-request PDUs
24 SNMP packets output
 0 Too big errors
 0 No such name errors
 0 Bad value errors
 0 General errors
 8 Response PDUs
 0 Trap PDUs
SNMP logging: enabled
 Logging to taccon.162
SNMP agent enabled
switch(config) #
```

---

#### 21.5.4.20 snmp-server enable traps

The **snmp-server enable traps** command enables Simple Network Management Protocol (SNMP) traps. The same command also enables SNMP inform requests. To specify the recipient for notifications, use the **snmp-server host** command. Sending notifications requires the configuration of at least one host using the **snmp-server host** command.

The **snmp-server enable traps** and **no snmp-server enable traps** commands, without a trap-type parameter, specify the default notification setting for all trap types. These commands, when specifying a trap type, control notification generation for the specified trap type. The **default snmp-server enable traps** command resets notification generation to the default setting for the specified trap type.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server enable traps [trap_type]
no snmp-server enable traps [trap_type]
default snmp-server enable trap [trap_type]
```

#### Parameters

**trap\_type** controls the generation of informs or traps for the specified trap type:

- **no parameter** controls notifications for traps not covered by specific commands.
- **entity** controls entity modification notifications.
- **lldp** controls LLDP notifications.
- **msdpBackwardTransition** controls msdpBackwardTransition notifications.
- **msdpEstablished** controls msdpEstablished notifications.
- **snmp** controls SNMP-v2 notifications.
- **switchover** controls switchover notifications.
- **snmpConfigManEvent** controls snmpConfigManEvent notifications.
- **test** controls test trap notifications.

#### Examples

- These commands enables notification generation for all trap types except entity traps.

```
switch(config)# snmp-server enable traps
switch(config)# no snmp-server enable traps entity
switch(config)#
```

- This command enables notification generation for all five entity traps, regardless of the default setting.

```
switch(config)# snmp-server enable traps entity
switch(config)#
```

- This command resets the entity trap notification generation to follow the default setting.

```
switch(config)# default snmp-server enable traps entity
switch(config)#
```

#### 21.5.4.21 snmp-server engineID local

The `snmp-server engineID local` command configures the name for the local Simple Network Management Protocol (SNMP) engine. The default SNMP engineID is generated by the switch and is used when an engineID is not configured with this command. The `show snmp engineID` command displays the default or configured engine ID.

SNMPv3 authenticates users through security digests (MD5 or SHA) that are based on user passwords and the local engine ID. Passwords entered on the CLI are similarly converted, then compared to the user's security digest to authenticate the user.

**Note:** Changing the local engineID value invalidates SNMPv3 security digests, requiring the reconfiguration of all user passwords.

The `no snmp-server engineID` and `default snmp-server engineID` commands restore the default engineID by removing the `snmp-server engineID` command from the *running-config*.

##### Command Mode

Global Configuration

##### Command Syntax

```
snmp-server engineID local engine_hex
no snmp-server engineID local
default snmp-server engineID
```

##### Parameter

***engine\_hex*** the switch name for the local SNMP engine (hex string).

The string must consist of at least ten characters with a maximum of **64** characters.

##### Example

This command configures **DC945798CAB4** as the name of the local SNMP engine.

```
switch(config)# snmp-server engineID local DC945798CAB4
switch(config)#
```

## 21.5.4.22 snmp-server engineID remote

The **snmp-server engineID remote** command configures the name of a Simple Network Management Protocol (SNMP) engine located on a remote device. The switch generates a default engineID; use the [show snmp engineID](#) command to view the configured or default engineID.

An SNMPv3 inform requires a remote engine ID to compute the security digest that authenticates and encrypts data transmitted to remote users. SNMPv3 authenticates users with MD5 or SHA through the engine ID and user passwords. CLI passwords are similarly authenticated.

**Note:** Changing the engineID value invalidates SNMPv3 security digests, requiring the reconfiguration of all user passwords.

The **no snmp-server engineID remote** and **default snmp-server engineID remote** commands remove the **snmp-server engineID remote** command from the configuration.

### Command Mode

Global Configuration

### Command Syntax

```
snmp-server engineID remote engine_addr [PORT] engine_hex
no snmp-server engineID remote engine_addr [PORT]
default snmp-server engineID remote engine_addr [PORT]
```

### Parameters

- ***engine\_addr*** location of remote engine (IP address or host name).
- **PORT** udp port location of the remote engine. Options include:
  - **no parameter** port number **161** (default).
  - **udp-port *port\_num*** port number. Ranges from **0** to **65535**.
- ***engine\_hex*** the switch's name for the remote SNMP engine (hex string).

The string must have at least ten characters and can contain a maximum of **64** characters.

### Example

This command configures **DC945798CA** as the engineID of the remote SNMP engine located at **10.23.10.25**, UDP **port 162**.

```
switch(config)# snmp-server engineID remote 10.23.10.25 udp-port 162 DC945798CA
switch(config)#
```

### 21.5.4.23 snmp-server extension

The **snmp-server extension** command configures the execution of user supplied scripts to service portions of the OID space.

The **no snmp-server extension** and **default snmp-server extension** commands deletes the **snmp-server extension** command from the **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server extension OID_space FILE_PATH [DURATION]
```

#### Parameters

- ***OID\_space*** OID branch serviced by the script, in numerical format.
- ***FILE\_PATH*** path and name of the script file. Options include:
  - **file:** file is located in the switch file directory.
  - **flash:** file is located in flash memory.
- **DURATION** the execution scope of the script.
  - **no parameter** script runs after initial request to process subsequent requests.
  - **one-shot** script processes a single object (runs once), then terminates.

#### Example

This command specifies the file example.sh, located in flash, as the script file that services the listed OID space.

```
switch(config)# snmp-server extension .1.3.6.1.4.1.8072.2 flash:example.sh
```

#### 21.5.4.24 snmp-server group

The **snmp-server group** command configures a new Simple Network Management Protocol (SNMP) group or modifies an existing group. An SNMP group is a data structure that user statements reference to map SNMP users to SNMP contexts and views, providing a common access policy to the specified users.

An SNMP context is a collection of management information items accessible by an SNMP entity. Each item of may exist in multiple contexts. Each SNMP entity can access multiple contexts. A context is identified by the EngineID of the hosting device and a context name.

The **no snmp-server group** and **default snmp-server group** commands delete the specified group by removing the corresponding **snmp-server group** command from the configuration.

##### Command Mode

Global Configuration

##### Command Syntax

```
snmp-server group group_name VERSION [CNTX][READ][WRITE][NOTIFY]
```

```
no snmp-server group group_name VERSION
```

```
default snmp-server group group_name VERSION
```

##### Parameters

- **group\_name** the name of the group.
- **VERSION** the security model utilized by the group.
  - **v1** SNMPv1. Uses a community string match for authentication.
  - **v2c** SNMPv2c. Uses a community string match for authentication.
  - **v3 no auth** SNMPv3. Uses a username match for authentication.
  - **v3 auth** SNMPv3. HMAC-MD5 or HMAC-SHA authentication.
  - **v3 priv** SNMPv3. HMAC-MD5 or HMAC-SHA authentication. AES or DES encryption.
- **CNTX** associates the SNMP group to an SNMP context.
  - **no parameter** command does not associate group with an SNMP context.
  - **context context\_name** associates group with context specified by **context\_name**.
- **READ** specifies read view for SNMP group.
  - **no parameter** command does not specify read view.
  - **read read\_name** read view specified by **read\_name** (string maximum 64 characters).
- **WRITE** specifies write view for SNMP group.
  - **no parameter** command does not specify write view.
  - **write write\_name** write view specified by **write\_name** (string maximum 64 characters).
- **NOTIFY** specifies notify view for SNMP group.
  - **no parameter** command does not specify notify view.
  - **notify notify\_name** notify view specified by **notify\_name** (string maximum 64 characters).

##### Example

This command configures **normal\_one** as SNMP version 3 group (authentication and encryption) that provides access to the **all-items read view**.

```
switch(config)# snmp-server group normal_one v3 priv read all-items
```

```
switch(config) #
```

---

#### 21.5.4.25 snmp-server host

The **snmp-server host** command configures an SNMP host to send SNMP traps and sets the community string if not previously configured. The host uses the host location and community string. The command also specifies the type of SNMP notifications to send. A trap consists of an unsolicited notification, and an inform consists of a trap that includes a request for a confirmation receipt of the message.

The configuration can contain multiple statements to the same host location with different community strings. For instance, a configuration can simultaneously contain all of the following:

- **snmp-server host host-1 version 2c comm-1**
- **snmp-server host host-1 informs version 2c comm-2**
- **snmp-server host host-1 version 2c comm-3 udp-port 666**
- **snmp-server host host-1 version 3 auth comm-3**

The **no snmp-server host** and **default snmp-server host** commands remove the specified host by deleting the corresponding **snmp-server host** statement from the configuration. When removing a statement, the host (address and port) and community string must be specified.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server host [host_id | ip_address] informs [udp-port dest_port] refresh traps
version [1 | 2c | 3] vrf vrf_name

no snmp-server host host_id informs [udp-port dest_port] refresh traps version [1
| 2c | 3] vrf vrf_name

default snmp-server host host_id
```

#### Parameters

- ***host\_id*** - Specify the hostname or IP address of the SNMP host.
- ***vrf\_instance*** - Specify the VRF instance to modify.
  - **no parameter** - Changes apply to the default VRF.
  - **vrf *vrf\_name*** - Changes apply to the specified user-defined VRF.
- **informs** sends SNMP informs to host.
- **traps** sends SNMP traps to host.
- **version *version*** - Specify the SNMP version. Options include the following parameters:
  - **no parameter** SNMPv2c (default).
  - **version 1** SNMPv1 - Not available with informs.
  - **version 2c** SNMPv2c.
  - **version 3 noauth** SNMPv3 - Enables user-name match authentication.
  - **version 3 auth** SNMPv3 - Enables MD5 and SHA packet authentication.
  - **version 3 priv** SNMPv3 - Specify HMAC-MD5 or HMAC-SHA authentication and AES or DES encryption.
- ***comm\_str*** community string to be sent with the notification as a password.

Arista recommends setting this string separately before issuing the **snmp-server host** command. To set the community string separately, use the [snmp-server community](#) command.

- ***port port*** - Specify the port number of the host.

- **no parameter** socket number set to **162** (default).
- **udp-port p-name** socket number specified by **p-name**.

## Guidelines

The switch can only send SNMP traps and informs if the configured host can receive them through an accessible interface in a VRF with SNMP enabled. SNMP is enabled by default only on the **default** VRF. Enable or disable SNMP in a VRF with the [snmp-server vrf](#) command.

## Example

This command adds a **version 2c** inform notification recipient.

```
switch(config)# snmp-server host 10.15.2.3 informs version 2c comm-1
switch(config)#[/pre]
```

---

#### 21.5.4.26 snmp-server local-interface

The **snmp-server local-interface** command specifies the interface where SNMP originates informs and traps.

The **no snmp-server local-interface** and **default snmp-server local-interface** commands remove the inform or trap source assignment by removing the **snmp-server local-interface** command from *running-config*.

##### Command Mode

Global Configuration

##### Command Syntax

```
snmp-server local-interface INTERFACE
no snmp-server local-interface
default snmp-server local-interface
```

##### Parameters

**INTERFACE** Interface type and number. Values include:

- **ethernet e\_num** Ethernet interface specified by **e\_num**.
- **loopback l\_num** Loopback interface specified by **l\_num**.
- **management m\_num** Management interface specified by **m\_num**.
- **port-channel p\_num** Port-Channel Interface specified by **p\_num**.
- **vlan v\_num** VLAN interface specified by **v\_num**.
- **vrf vrf\_name** The VRF in which SNMP is enabled. The keyword **default** specifies the default VRF.

##### Example

This command configures *interface ethernet 1* as the source of SNMP traps and informs.

```
switch(config)# snmp-server local-interface ethernet 1
switch(config) #
```

#### 21.5.4.27 snmp-server location

The **snmp-server location** command configures the system location string. By default, no system location string is set.

The **no snmp-server location** and **default snmp-server location** commands delete the location string by removing the **snmp-server location** command from the configuration.

##### Command Mode

Global Configuration

##### Command Syntax

```
snmp-server location node_locate
no snmp-server location
default snmp-server location
```

##### Parameters

***node\_locate*** system location information (string).

##### Example

These commands configure **lab-east** as the location string.

```
switch(config)# snmp-server location lab_east
switch(config)#
```

#### 21.5.4.28 snmp-server qosmib counter-interval

The **snmp-server qosmib counter-interval** command configures the interval (in seconds) after which the QoS counters are updated periodically. By default the counter updates are disabled.

##### Command Mode

Global Configuration

##### Command Syntax

```
snmp-server qosmib counter-interval timer_interval
no snmp-server qosmib counter-interval
default snmp-server qosmib counter-interval
```

##### Parameter

***timer\_interval*** Update interval for refreshing QoS counters (in seconds) between (**10-600**).

##### Example

The following command configures a interval of **50** seconds after which the QoS counters are updated periodically.

```
switch(config)# snmp-server qosmib counter-interval 50
```

#### 21.5.4.29 snmp-server user

The **snmp-server user** command adds a user to a Simple Network Management Protocol (SNMP) group or modifies an existing user's parameters.

To configure a user, the IP address or port number of the device where the user's remote SNMP agent resides must be specified. A user's authentication come from the engine ID and the user's password. Remote user configuration commands fail if the remote engine ID is not configured first.

The **no snmp-server user** and **default snmp-server user** commands remove the user from an SNMP group by removing the user command from *running-config*.

**Note:** Use the following minimums when using the stronger SNMPv3 encryption algorithm to avoid any interoperability issues.

- When using AES-192 for encryption/privacy, use a minimum of SHA-224 for authentication.
- When using AES-256 for encryption/privacy, use a minimum of SHA-256 for authentication.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server user user_name group_name [AGENT] VERSION [ENGINE][SECURITY]
no snmp-server user user_name group_name [AGENT] VERSION
default snmp-server user user_name group_name [AGENT] VERSION
```

#### Parameters

- **user\_name** name of user.
- **group\_name** name of group to which user is being added.
- **AGENT** Options include:
  - **no parameter** local SNMP agent.
  - **remote addr [udp-port p\_num]** remote SNMP agent location.
- **addr** denotes the IP address; **p\_num** denotes the udp port socket (default port is **162**).
- **VERSION** SNMP version; options include:
  - **v1** SNMPv1.
  - **v2c** SNMPv2c.
  - **v3** SNMPv3.
- **ENGINE** engine ID used to localize passwords. Available only if **VERSION** is **v3**.
  - **no parameter** Passwords localized by SNMP copy specified by **agent**.
  - **localized enginID** octet string of enginID.
- **SECURITY** Specifies authentication and encryption levels. Available only if **VERSION** is **v3**. Encryption is available only when authentication is configured.
  - **no parameter** no authentication or encryption.
  - **auth a\_meth a\_pass [priv e\_meth e\_pass]** authentication parameters.
  - **a\_meth** authentication method: options are **md5** (HMAC-MD5-96) and **sha** (HMAC-SHA-96).
  - **a-pass** authentication string for users receiving packets.
  - **e-meth** encryption method: Options are **aes** (AES-128) and **des** (CBC-DES).
  - **e-pass** encryption string for the users sending packets.

## Example

This command configures the remote SNMP user **tech-1** to the **tech-sup** SNMP group.

```
switch(config)# snmp-server user tech-1 tech-sup remote 10.1.1.2 v3
```

---

#### 21.5.4.30 snmp-server view

The **snmp-server view** command defines a view.

An SNMP view defines a subset of objects from an MIB. Every SNMP access group specifies views, each associated with read or write access rights, to allow or limit the group's access to MIB objects.

The **no snmp-server view** command deletes a view entry by removing the corresponding **snmp-server view** command from the **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server view view_name [family_name] INCLUSION
no snmp-server view view_name [family_name]
default snmp-server view view_name [family_name]
```

#### Parameters

- ***view\_name*** Label for the view record that the command updates. Other commands reference the view with this label.
- ***family\_name*** name of the MIB object or family.  
MIB objects and MIB subtrees can be identified by name or by the numbers representing the position of the object or subtree in the MIB hierarchy.
- **INCLUSION** inclusion level of the specified family within the view. Options include:
  - **include** view includes the specified subtree.
  - **exclude** view excludes the specified subtree.

#### Example

These commands create a view named **sys-view** that includes all objects in the **system subtree** except for those in **system.2**.

```
switch(config) # snmp-server view sys-view system include
switch(config) # snmp-server view sys-view system.2 exclude
```

### 21.5.4.31 snmp-server vrf

The **snmp-server vrf** command enables SNMP in the specified VRF. By default, SNMP is enabled only in **default** VRF.

- User-defined VRFs: The **no snmp-server vrf** command disables SNMP in the specified VRF by removing the corresponding **snmp-server vrf** command from the **running-config**.
- Default VRF: The **no snmp-server vrf** command disables SNMP in the VRF by adding a **no snmp-server vrf default** statement to the **running-config**.

#### Command Mode

Global Configuration

#### Command Syntax

```
snmp-server vrf vrf_name
no snmp-server vrf vrf_name
default snmp-server vrf vrf_name
```

#### Parameters

**vrf\_name** The VRF in which SNMP is enabled. The keyword **default** specifies the default VRF.

#### Guidelines

The switch can only send SNMP traps and informs if the host that has been configured to receive them is accessible through an interface in a VRF in which SNMP has been enabled. SNMP is enabled by default only in the **default** VRF. Enable or disable SNMP in a VRF with the **snmp-server vrf** command.

#### Example

These commands disable SNMP in the default VRF, then enable it in the user-defined VRFs named **magenta** and **columbia**.

```
switch(config) # no snmp-server vrf default
switch(config) # snmp-server vrf magenta
switch(config) # snmp-server vrf columbia
switch(config) #
```

## 21.6 VM Tracer

This chapter describes VM Tracer configuration and usage and contains these sections:

- [Introducing VM Tracer](#)
- [VM Tracer Description](#)
- [VM Tracer Configuration Procedures](#)
- [VM Tracer Commands](#)

---

## 21.6.1 Introducing VM Tracer

VM Tracer determines the network configuration and requirements of connected VMware hypervisors. The switch uses the VMware SOAP XML API to discover VMware host server components, including the following:

- Instantiated VMs with the network configuration, including VLANs and distributed or virtual switches.
- Provide server hardware IPMI data to the network manager.

VM Tracer also supports adaptive auto-segmentation, which automatically provisions and prunes VLANs from server-switched ports as VMs are instantiated and moved within the data center.

## 21.6.2 VM Tracer Description

Cloud operating systems manage large virtualized computing infrastructures, including software and hardware. Cloud operating systems consist of virtual machines and hypervisors:

- A Virtual Machine (VM) contains software that emulates a computer running on dedicated physical hardware. Multiple VMs share physical computer resources from a single physical device. The operating system controls each VM.
- A hypervisor, a Virtual Machine Manager (VMM), manages multiple operating systems running concurrently on a physical device.

VM Tracer tracks the activity of VMs controlled by hypervisors connected to the switch Ethernet or LAG ports. It supports vSphere versions 6.0– 7.0. The vSphere features include Distributed Virtual Switches (DVS) and VM movement among VMware servers (VMotion).

vSphere components includethe following:

- ESX and ESXi - Hypervisors that run on VMware host server hardware.
- vCenter - A centralized tool that manages multiple servers running VMware hypervisors.
- NSX for vSphere® (NSX-V) - A network virtualization platform delivering networking and security.

Monitoring VLAN based configurations requires vCenter access. Monitoring VXLAN-based configurations requires access to vCenter and NSX-V. The following sections describe topologies that monitor these networks:

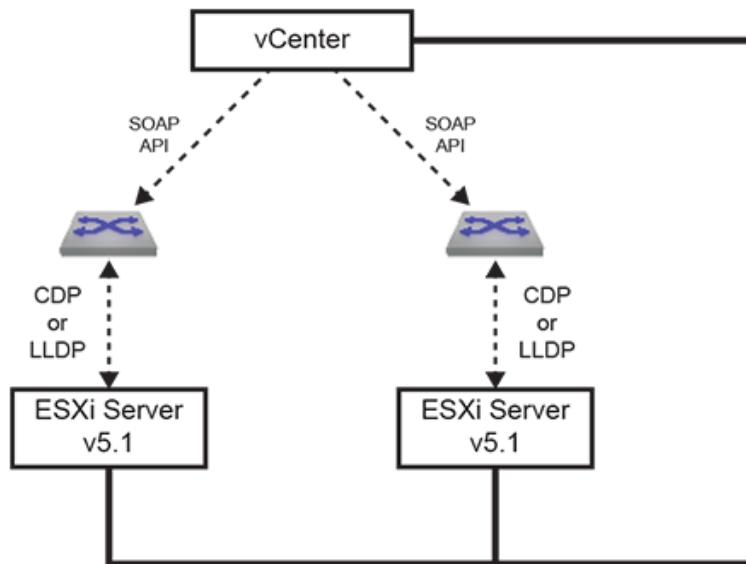

- [Monitoring VLAN-based Configurations](#)
- [Monitoring VXLAN-based Configurations](#)

### 21.6.2.1 Monitoring VLAN-based Configurations

vCenter manages ESX hosts and VMs through a central database. VM Tracer identifies interfaces connected to a specified ESX host and sends discovery packets (CDP or LLDP) on interfaces where VM Tracer is enabled. The ESX host updates the vCenter when it receives a discovery packet. VM Tracer reads this data

from the vCenter through a SOAP (Simple Object Access Protocol) XML API to associate the ESX host to the connected switch ports. The following figure displays the network topology of this configuration.

**Figure 21-3: VM Tracer Topology – Monitoring VLAN Based Configurations**

VM Tracer connects to a maximum of four vCenters through a SOAP XML API to discover VMs in the data centers managed by the vCenters. VM Tracer maintains a list of VMs in the data center and collects network-related information about each VM, including the number of Vnics (virtual network interface card), each Vnic MAC address, the connected switch, and the host on which it resides. VM Tracer also identifies the host NICs connected to the switch through the bridge MAC address and the interface port name. VM Tracer then searches for VMs on this host and connects to the vswitch or dvswitch with the uplink mapped to the connected NIC.

VM Tracer creates a VM Table for each connected interface that lists the active VMs, sorted by Vnic MAC address. Each VM entry includes the name, Vnic name, VLAN, switch name, datacenter name, and port group. The VM Table deletes the VM entry after removing the corresponding VM, moving the VM to a different host, or the Vnic no longer exists as part of the vswitch or dvswitch. The VM Table adds an entry after creating a VM or moving a VM to a host connected to the interface. VM Tracer monitors vCenter for VM management updates. If an interface goes down, the VM Table removes all VM entries for that interface.

### 21.6.2.2 Monitoring VXLAN-based Configurations

Monitoring VXLAN-based configurations require access to the NSX for vSphere® (NSX-V), in addition to the configuration described in [Monitoring VLAN-based Configurations](#). Each VM Tracer session can communicate with one NSX-V through a REST interface over XML and gathers VXLAN information by polling it on a 30-second polling cycle. VXLAN data that the switch receives from the NSX-V includes the following:

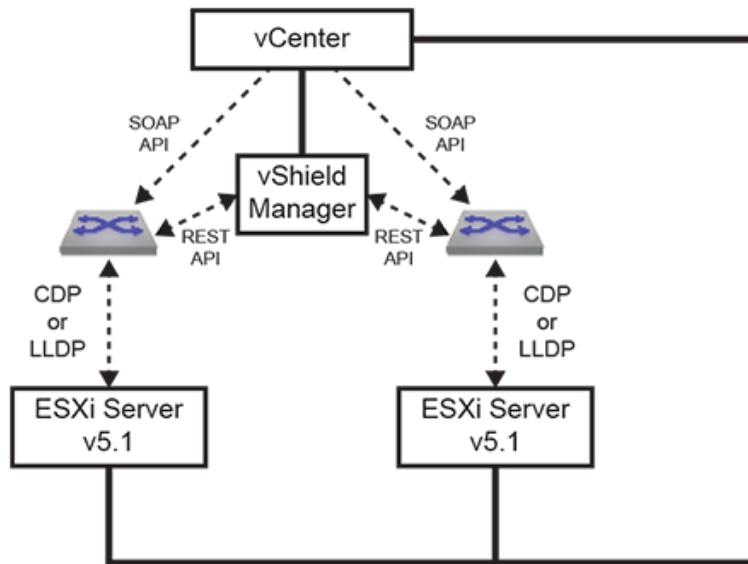

- VNI range
- VXLAN segment
- Multicast address range
- Network scope

The network scope specifies the virtual address space that the VXLAN segments span and the server group (cluster) collections within the segments, which in turn contain a collection of distributed virtual switches (DVS) from ESX hosts within the clusters.

VM Tracer uses this information to build a network model. Communications with NSX-V require a single polling thread that detects network connectivity and constantly updates the local data model.

The following diagram displays the network topology of this configuration.

**Figure 21-4: VM Tracer Topology – Monitoring VXLAN Based Configurations**

## 21.6.3 VM Tracer Configuration Procedures

The following sections describe the session configuration process, configuring the NSX-V connection for VXLAN based configurations, and the procedure for enabling VM Tracer on individual interfaces. The switch defines the **vmtracer** configuration mode and VMtracer mode:

- **vmtracer** configuration mode is a command mode for configuring VM Tracer monitoring sessions.
- VMtracer mode defines an interface state that sends discovery packets to attached vSwitches.

### 21.6.3.1 Configuring vCenter Monitoring Sessions

A VM Tracer session connects the switch to a vCenter server for downloading data about VMs and vSwitches managed by ESX hosts connected to the switch ports. The switch supports four VM Tracer sessions.

Place the switch in the **vmtracer** configuration mode to edit session parameters, including the vCenter location and dynamic VLAN usage. Changes take effect by exiting **vmtracer** configuration mode.

The **vmtracer session** command places the switch in the **vmtracer** configuration mode for a specified session. The command either creates a new session or loads an existing session for editing.

#### Example

This command enters the **vmtracer** configuration mode for the **system\_1** session.

```
switch(config)# vmtracer session system_1
switch(vmtracer-system_1) #
```

In **vmtracer** configuration mode, the **url** (**vmtracer mode**), **username**, and **password** commands specify the location and the account information that authenticates the switch. The URL parameter must reference a fully formed secure URL.

## Example

These commands specify the IANA url along with the username and password that allow the switch to access the location.

```
switch(vmtracer-system_1) # url https://example.com/sdk
switch(vmtracer-system_1) # username a-switch_01
switch(vmtracer-system_1) # password abcde
switch(vmtracer-system_1) #
```

Default session settings permit auto-segmentation, or the dynamic allocation and pruning of VLANs when creating, deleting, or moving a VM managed by the ESX host to a different host. The **autovlan disable** command prevents auto-segmentation, regardless of VM activity. The **allowed-vlan** command specifies the available VLANs when adding or moving a VM. By default, all VLANs are allowed.

## Examples

- This command disables auto-segmentation.

```
switch(vmtracer-system_1) # autovlan disable
switch(vmtracer-system_1) #
```

- These commands enable auto-segmentation and limit the list of allowed VLANs to **VLAN 1-2000**.

```
switch(vmtracer-system_1) # no autovlan disable
switch(vmtracer-system_1) # allow-vlan 1-2000
switch(vmtracer-system_1) #
```

The **exit** command returns the switch to the **global** configuration mode and enables the VM Tracer session. The **vmtracer** configuration mode can be re-entered for this session to edit session parameters.

## Example

This command exits **vmtracer** configuration mode.

```
switch(vmtracer-system_1) # exit
switch(config) #
```

The **no vmtracer session** command disables the session and removes it from **running-config**.

## Example

This command disables and deletes the **system\_1** VM Tracer session.

```
switch(config) # no vmtracer session system_1
switch(config) #
```

### 21.6.3.2 Configuring vShield Monitoring Sessions

The switch must communicate with an NSX for vSphere® (NSX-V) to monitor VXLAN-based VMware configurations. The **vmtracer-VXLAN** configuration mode specifies the location and user account data that permits the switch to access an NSX-V within the configuration mode vmtracer session.

Place the switch in the **vmtracer** configuration mode to edit session parameters, including the vCenter location and dynamic VLAN usage. Changes take effect by exiting vmtracer mode.

Execute the **vxlan** command from the **vmtracer** mode for a specified session and places the switch in the **vmtracer-VXLAN** configuration mode for that session. Each VM Tracer session can be associated with one vShield instance.

## Example

These commands create the vShield instance for the VMTracer session named **vnet-1**.

```
switch(config)# vmtracer session vnet-1
switch(config-vmtracer-vnet-1)# vxlan
switch(config-vmtracer-vnet-1-vxlan) #
```

In the **vmtracer-vxlan** configuration mode, the [url](#), [username](#) (**vmtracer-vxlan mode**), and [password](#) (**vmtracer-VXLAN mode**) commands specify the vShield server location and the account information that authenticates the switch to the vShield server. The url parameter must reference a fully formed secure url, such as <https://vcshield.democorp.com/sdk>.

## Example

These commands specify the vShield URL along with the username and password that allow the switch to access the vShield server.

```
switch(config-vmtracer-vnet-1-vxlan) # url https://vshieldserver.company1.org/sdk
switch(config-vmtracer-vnet-1-vxlan) # username a-shield_01
switch(config-vmtracer-vnet-1-vxlan) # password home
switch(config-vmtracer-vnet-1-vxlan) #
```

### 21.6.3.3 Enabling VMtracer Mode

VMtracer mode provides an interface setting that enables interfaces to send discovery packets to the connected vSwitch. The **vmtracer** command enables VMtracer mode on the configuration mode interface.

#### Examples

- These commands enable VMtracer mode on the **interface Ethernet3**.

```
switch(config)# interface Ethernet3
switch(config-if-Et3)# vmtracer vmware-esx
switch(config-if-Et3) #
```

The **no vmtracer** command disables vmtracer mode on the configuration mode interface.

- This command disables vmtracer mode on the **interface ethernet 3**.

```
switch(config-if-Et3)# no vmtracer vmware-esx
switch(config-if-Et3) #
```

### 21.6.3.4 Displaying VM Tracer Data

#### 21.6.3.4.1 Displaying Session Status

The **show vmtracer session** command displays information about the specified session.

Without the **detail** parameter, the command displays connection parameters and status for the vCenter associated to the specified session.

## Example

This command displays connection parameters for the vCenter associated with the system\_1 session.

```
switch# show vmtracer session system_1
```

```
vCenter URL https://vmware-vcenter1/sdk
username arista
password arista
Session Status Disconnected
```

With the **detail** parameter, the command displays connection status and data concerning messages the vCenter previously received from ESX hosts connected to the switch.

### Example

This command displays connection parameters and message details for the vCenter associated with the **system\_1** session.

```
switch# show vmtracer session system_1 detail
vCenter URL https://vmware-vcenter1/sdk
username arista
sessionState Connected
lastStateChange 19 days, 23:03:59 ago
lastMsgSent CheckForUpdatesMsg
timeOfLastMsg 19 days, 23:14:09 ago
resonseTimeForLastMsg 0.0
numSuccessfulMsg 43183
lastSuccessfulMsg CheckForUpdatesMsg
lastSuccessfulMsgTime 19 days, 23:14:19 ago
numFailedMsg 1076
lastFailedMsg CheckForUpdatesMsg
lastFailedMsgTime 19 days, 23:14:09 ago
lastErrorCode Error -1 fault: SOAP-ENV:Client [no subcode]
"End of file or no input: Operation interrupted or timed out after 600s send
or 600s receive delay"
Detail: [no detail]
CheckForUpdates:
```

### 21.6.3.4.2 Displaying VM Interfaces

The **show vmtracer interface** command displays the VM interfaces (Vnics) active on switch interfaces with vmtracer mode enabled. For each Vnic, the command displays the name of the attached VM, the adapter name, the VLAN, the VM power state, and the presence status of its MAC address in the switch MAC table.

This command displays the Vnics connected to all VM Tracer-enabled interfaces.

```
switch# show vmtracer interface

Ethernet8 : example.com
 VM Name VM Adapter VLAN Status
 esx3.aristanetworks.com vmk0 0 Up/Down
 vspheremanagement Network adapter 1 0 Up/Down

Ethernet15 : example.om
 VM Name VM Adapter VLAN Status
 Openview Network adapter 1 123 Up/Down
 VmTracerVm Network adapter 1 123 Down/Down

Ethernet23 : example.com
 VM Name VM Adapter VLAN Status

Ethernet24 : example.com
 VM Name VM Adapter VLAN Status
```

### 21.6.3.4.3 Displaying VMs

The **show vmtracer vm** command displays VM interfaces (Vnics) accessible to the VM Tracer-enabled interfaces. For each active listed VM, the command displays the name, adapter, and the connected hypervisor.

- 
- This command displays the VMs connected to all VM Tracer-enabled interfaces.

```
switch# show vmtracer vm
VM Name VM Adapter Interface VLAN
 Openview Network adapter 1 Et15 123
 vspheremanagement Network adapter 1 Et8 0
 VmTracerVm Network adapter 1 Et15 123
example.com vmk0 Et8 0
```

- This command displays connection data for the VMs connected to all VM Tracer-enabled interfaces.

```
switch# show vmtracer vm detail
VM Name Openview
 intf : Et15
 vnic : Network adapter 1
 mac : 00:0c:29:ae:7e:90
 portgroup : dvPortGroup
 vlan : 123
 switch : vds
 host : example.com
```

## 21.6.4 VM Tracer Commands

### Global Configuration Commands

- [vmtracer session](#)

### Interface Configuration (Ethernet and Port Channel) Commands

- [vmtracer](#)

### VMTracer Configuration Commands

- [allowed-vlan](#)
- [autovlan disable](#)
- [password](#)
- [source-interface](#)
- [url \(vmtracer mode\)](#)
- [username \(vmtracer mode\)](#)
- [vrf \(vmtracer mode\)](#)
- [vxlan \(vmtracer mode\)](#)

### VMTracer-VXLAN Configuration Commands

- [password \(vmtracer-vxlan mode\)](#)
- [url \(vmtracer-vxlan mode\)](#)
- [username \(vmtracer-vxlan mode\)](#)

### VM Tracer Display Commands

- [show vmtracer all](#)
- [show vmtracer interface](#)
- [show vmtracer session](#)
- [show vmtracer session vcenter](#)
- [show vmtracer session vsm](#)
- [show vmtracer vm](#)
- [show vmtracer vm detail](#)
- [show vmtracer vnic counters](#)
- [show vmtracer vxlan segment](#)
- [show vmtracer vxlan vm](#)

---

#### 21.6.4.1 allowed-vlan

The **allowed-vlan** command specifies the VLANs that may be added when adding or moving a VM from the hypervisor connected to the session specified by the vmtracer mode. By default, all VLANs are allowed.

##### Command Mode

Vmtracer Configuration

##### Command Syntax

```
allowed-vlan [VLAN_LIST]
```

```
no allowed-vlan
```

```
default allowed-vlan vlan
```

##### Parameters

**VLAN\_LIST** The VLAN list or the edit actions to the current VLAN list. Valid **v\_range** formats include number, or number range.

- **v\_range** The list consists of the **v\_range** VLANs.
- **add v\_range** The **v\_range** VLANs are added to the current VLAN list.
- **all** The list consists of all VLANs (**1-4094**).
- **except v\_range** The list consists of all VLANs except for those specified by **v\_range**.
- **none** The list of VLANs is empty.
- **remove v\_range** The **v\_range** VLANs are removed from the current VLAN list.

##### Related Command

`vmtracer session`[vmtracer session](#) places the switch in the **vmtracer** configuration mode.

##### Examples

- This command sets the list of allowed VLANs to **1** through **2000**.

```
switch(vmtracer-system_1) # allow-vlan 1-2000
switch(vmtracer-system_1) #
```

- This command adds VLANs to **2501** through **3000**.

```
switch(vmtracer-system_1) # allow-vlan add 2051-3000
switch(vmtracer-system_1) #
```

#### 21.6.4.2 **autovlan disable**

Default VM Tracer session settings enable auto provisioning, which allows the dynamic assignment and pruning of VLANs when creating, deleting, or moving a VM attached to the ESX connected to the switch to a different ESX host. The **autovlan disable** setting controls auto provisioning.

The **autovlan disable** command disables auto provisioning, which prevents the creation or deletion of VLANs regardless of VM activity. The **allowed-vlan** command specifies the VLANs that may be added when a VM is added or moved. By default, all VLANs are allowed.

The **no autovlan disable** command enables the creation and deletion of VLANs caused by VM activity. This is the default setting.

##### **Command Mode**

Vmtracer Configuration

##### **Command Syntax**

```
autovlan disable
no autovlan disable
default autovlan disable
```

##### **Related Command**

[vmtracer session](#) places the switch in the **vmtracer** configuration mode.

##### **Example**

This command disables dynamic VLAN creation or pruning within the configuration mode VM Tracer session.

```
switch(vmtracer-system_1) # autovlan disable
switch(vmtracer-system_1) #
```

#### 21.6.4.3 **password**

The **password** command specifies the token that authorizes the username to the vCenter associated with the VM Tracer mode session.

##### **Command Mode**

Vmtracer Configuration

##### **Command Syntax**

```
password [ENCRYPTION] [password]
```

##### **Parameters**

- **ENCRYPTION** - Encryption level of the password.
  - **no parameter** - The password in a clear-text string.
  - **0** - The password in a clear-text string. Equivalent to **no parameter**.
  - **7** the password is an encrypted string.
- **password** - Text that authenticates the username.
  - **password** is a clear-text string if **ENCRYPTION** specifies clear text.
  - **password** is an encrypted string if **ENCRYPTION** specifies an encrypted string.

---

## Related Command

[vmtracer session](#) places the switch in the **vmtracer** configuration mode.

## Example

This command configures **abode** as the clear-text string that authorizes the username **a-switch\_01** located at **example.com/sdk**.

```
switch(vmtracer-system_1) # url https://example.com/sdk
switch(vmtracer-system_1) # username a-switch_01
switch(vmtracer-system_1) # password abcde
switch(vmtracer-system_1) #
```

#### 21.6.4.4 password (vmtracer-VXLAN mode)

The **password** command specifies the token that authorizes the username on the NSX for vSphere® (NSX-V) server located at the URL configured for the configuration mode VM Tracer. The switch uses this account to access NSX-V information.

The **password** statement is replaced in *running-config* for the configuration mode interface by a subsequent **password** command. The statement is removed by deleting the NSX-V instance through a **vxlan** command in vmtracer configuration mode.

#### Command Mode

Vmtracer-VXLAN Configuration

#### Command Syntax

```
password [ENCRYPTION] password
```

#### Parameters

- **ENCRYPTION** encryption level of the password.
  - **no parameter** password is a clear-text string.
  - **0** the is a clear-text string. Equivalent to **no parameter**.
  - **7** the password is an encrypted string.
- **password** text that autorizes the username.
  - **password** is a clear-text string if **ENCRYPTION** specifies clear text.
  - **password** is an encrypted string if **ENCRYPTION** specifies an encrypted string.

#### Related Commands

**vxlan** places the switch in the **vmtracer-vxlan** configuration mode.

#### Example

This command configures **5678** as the clear-text string that authorizes the username **admin** to the NSX-V located at **https://example.com/sdk**.

```
switch(config)# vmtracer session vnet-1
switch(config-vmtracer-vnet-1)# vxlan
switch(config-vmtracer-vnet-1-vxlan)# url https://example.com/sdk
switch(config-vmtracer-vnet-1-vxlan)# username admin
switch(config-vmtracer-vnet-1-vxlan)# password 5678
switch(config-vmtracer-vnet-1-vxlan)# exit
switch(config-vmtracer-vnet-1)# show active
vmtracer session vnet-1
 allowed-vlan 1-4094
 vxlan
 url https://example.com/sdk
 username admin
 password 7 s2Xq4GSBLYU=
switch(config-vmtracer-vnet-1) #
```

#### 21.6.4.5 show vmtracer all

The **show vmtracer all** command displays VM Tracer data for all switches with the vSphere scope.

#### Command Mode

EXEC

## Command Syntax

```
show vmtracer all
```

## Example

This command displays data for both switches in the vSphere scope.

```
switch> show vmtracer all
Switch : a109(10.10.30.109)
Ethernet49 : 10.102.28.3/10G
 VM Name VM Adapter VLAN Status State
 ABCD Network adapter 2 native Up/-- --
Switch : a164(10.10.30.(172.22.30.164)
Ethernet49 : 10.102.28.3/10G Storage Network/dvUplink1
 VM Name VM Adapter VLAN Status State
 WXYZ Network adapter 2 native Up/-- --
switch>
```

### 21.6.4.6 show vmtracer interface

The **show vmtracer interface** command displays the VM interfaces (Vnics) active on the VM Tracer enabled interface. For each Vnic, the command displays the name of the attached VM, the adapter name, its VLAN, the VM power state, and the presence status of its MAC address in the switch MAC table.

#### Command Mode

EXEC

#### Command Syntax

```
show vmtracer interface [INT_NAME] [INFO_LEVEL]
```

#### Parameters

- **INT\_NAME** the interfaces to be configured. Values include:
  - **no parameter** command returns information for all interfaces.
  - **ethernet e\_range** Ethernet interface range.
  - **port-channel p\_range** Port Channel interface range.  
Valid **e\_range** and **p\_range** formats include number, number range, or comma-delimited list of numbers and ranges.
- **INFO\_LEVEL** specifies information that the command returns.
  - **no parameter** connection parameters and status for VM associated to specified sessions.
  - **detail** connection status and data concerning messages the VM.
  - **host** name of the connected host.

#### Examples

- This command displays the Vnics connected to all VM Tracer enabled interfaces.

```
switch > show vmtracer interface

Ethernet8 : example.com
 VM Name VM Adapter VLAN Status
 esx3.aristanetworks.com vmk0 0 Up/Down
 vspheremanagement Network adapter 1 0 Up/Down

Ethernet15 : example.com
 VM Name VM Adapter VLAN Status
 Openview Network adapter 1 123 Up/Down
 VmTracerVm Network adapter 1 123 Down/Down
```

```
Ethernet23 : example.com
VM Name
```

```
VM Adapter
```

```
VLAN
```

```
Status switch>
```

- This command displays the Vnics connected to the **interface Ethernet8**.

```
switch> show vmtracer interface Ethernet8
```

```
Ethernet8 : example.com
VM Name
example.com
vspheremanagement
```

```
VM Adapter
```

```
VLAN
```

```
Status
```

```
vmk0
```

```
0
```

```
Up/Down
```

```
Network adapter 1
```

```
0
```

```
Up/Down switch>
```

#### 21.6.4.7 show vmtracer session

The `show vmtracer session` command displays vCenter and vShield connection information for a specified VM Tracer session.

##### Command Mode

EXEC

##### Command Syntax

```
show vmtracer session [SESSION_LIST]
```

##### Parameters

**SESSION\_LIST** VM Tracer sessions for which the command returns information.

- **no parameter** all configured VM Tracer sessions.
- **session\_name** name of one VM Tracer session.

##### Example

This command displays connection parameters associated to the **abcde** session.

```
switch> show vmtracer session abcde
Session abcde
vCenter URL https://example.com/sdk
username Administrator
autovlan enabled
allowed-vlans 1-4094
sessionState Connected
VShield URL https://vmware-vshield5.1.xyz.abcde.com
username admin
sessionState Connected switch>
```

#### 21.6.4.8 show vmtracer session vcenter

The `show vmtracer session vcenter` command displays vCenter information for a specified VM Tracer session.

##### Command Mode

EXEC

##### Command Syntax

```
show vmtracer session session_name vcenter [INFO_LEVEL]
```

##### Parameters

- **session\_name** VM Tracer sessions for which the command returns information.
- **INFO\_LEVEL** specifies information that the command returns.
  - **no parameter** displays connection and status information for the specified vCenter.
  - **detail** displays connection, status, and history information for the specified vCenter.

##### Examples

- This command displays connection parameters for the vCenter associated to the abcde session.

```
switch> show vmtracer session abcde vcenter
```

```

Session abcde
vCenter URL https://vmware-vcenter5.1/sdk
username Administrator
autoVlan enabled
allowed-vlans 1-4094
sessionState Connected switch>

```

- This command displays connection parameters and history details from the vCenter associated to the **abcde** session.

```

switch> show vmtracer session abcde vcenter detail

Session abcde
vCenter URL https://vmware-vcenter5.1/sdk
username Administrator
autoVlan enabled
allowed-vlans 1-4094
SessionState Connected
lastStateChange 2:46:50 ago
lastMsgSent Query network hint message
timeOfLastMsg 0:00:20 ago
responseTimeForLastMsg 0.000102301000479
numSuccessfulMsg 998
lastSuccessfulMsg Query network hint message
lastSuccessfulMsgTime 0:00:20 ago
numFailedMsg 0
lastFailedMsg --
lastFailedMsgTime never
lastErrorCode --
switch>

```

#### 21.6.4.9 show vmtracer session vsm

The **show vmtracer session vsm** command displays NSX-V information for a specified VM Tracer session.

##### Command Mode

EXEC

##### Command Syntax

```
show vmtracer session session_name vsm [INFO_LEVEL]
```

##### Parameters

- session\_name** VM Tracer sessions for which the command returns information.
- INFO\_LEVEL** specifies information that the command returns.
  - no parameter** connection and status information for the specified NSX-V.
  - detail** connection, status, and history information for the specified NSX-V.

##### Examples

- This command displays connection parameters for the NSX-V associated to the **abcde** session.

```

switch> show vmtracer session abcde vsm

Session abcde
VShield URL https://example.com/sdk
username admin
sessionState Connected switch>

```

- This command displays connection parameters and history details from the vShield Manager associated to the **abcde** session.

```
switch> show vmtracer session abcde vsm detail

Session abcde
VShield URL https://vmware-vshield5.1/
username admin
SessionState Connected
LaststateChange 19 days, 23:14:19 ago

switch>
```

#### 21.6.4.10 show vmtracer vm

The **show vmtracer vm** command displays VMs interfaces (Vnics) accessible to VM Tracer enabled interfaces. For each active VM, the command displays the name of the VM, its adapter, and the hypervisor to which it connects.

##### Command Mode

EXEC

##### Command Syntax

**show vmtracer [INT\_NAME] vm [VM\_LIST]**

##### Parameters

- **INT\_NAME** the interfaces name Values include:
  - **no parameter** command returns information for all interfaces.
  - **interface ethernet e\_range** Ethernet interface range.
  - **interface port-channel p\_range** Port Channel interface range.
 Valid **e\_range** and **p\_range** formats include a number, number range, or comma-delimited list of numbers and ranges.
- **VM\_LIST** The virtual machines for which the command displays information. Options include:
  - **no parameter** command returns information for all present VMs.
  - **vm\_name** command returns information only for specified VM.

##### Related Command

The [show vmtracer vm detail](#) command displays connection information for one or more specified VMs.

##### Example

This command displays the VMs connected to all VM Tracer enabled interfaces.

| switch> show vmtracer vm |             |           |        |           |
|--------------------------|-------------|-----------|--------|-----------|
| VM Name                  | Esx Host    | Interface | VLAN   | Status    |
| vCenter1                 | 172.22.28.8 | Po45      | native | Down/Down |
| vCenter2                 | 172.22.28.8 | Po45      | native | Up/Up     |

|                      |             |      |        |               |
|----------------------|-------------|------|--------|---------------|
| vCenter3             | 172.22.28.8 | Po45 | 11     | Down/Down     |
| vCenter4             | 172.22.28.8 | Po45 | native | Down/Down     |

---

#### 21.6.4.11 show vmtracer vm detail

The **show vmtracer vm detail** command displays connection data for VMs interfaces (Vnics) accessible to VM Tracer enabled interfaces.

##### Command Mode

EXEC

##### Command Syntax

```
show vmtracer vm [VM_LIST] detail
```

##### Parameters

**VM\_LIST** The virtual machines for which the command displays information. Options include:

- **no parameter** command returns information for all present VMs.
- **vm\_name** command returns information only for specified VM.

##### Examples

- This command displays connection data for the VMs connected to all VM Tracer enabled interfaces.

```
switch# show vmtracer vm vmcenter1
VM Name vCenter1 Server App
 Interface : Po45
 vNIC : Network adapter 1
 MAC : 00:31:22:8e:b8:41
 Portgroup : VM Network
 VLAN : native
 Switch : Switch2
 Status : Down/Down
 Host : 10.22.18.28
 Data Center : vcenter-5 switch>
```

- This command displays connection data for the VMs connected to all VM Tracer enabled interfaces.

```
switch> show vmtracer vm detail
VM Name vCenter1 Server App
 Interface : Po45
 vNIC : Network adapter 1
 MAC : 00:31:22:8e:b8:41
 Portgroup : VM Network
 VLAN : native
 Switch : Switch2
 Status : Down/Down
 Host : 10.22.18.28
 Data Center : vcenter-5

VM Name vCenter2 Server App
 Interface : Po45
 vNIC : vmk0
 MAC : 00:33:23:3c:e1:4e
 Portgroup : Management Network
 VLAN : native switch>
```

#### 21.6.4.12 show vmtracer vnic counters

The **show vmtracer interface vnic counters** command displays input and output packet counts for VM interfaces (Vnics) active on the specified interface or VM.

##### Command Mode

EXEC

##### Command Syntax

```
show vmtracer [ENTITY] vnic counters
```

##### Parameters

**ENTITY** the virtual machine or interface over which statistics are gathered and displayed.

- **no parameter** command returns information for all active VMs.
- **interface ethernet e\_range** Ethernet interface range.
- **interface port-channel p\_range** Port Channel interface range.
- **vm vm\_name** command returns information for specified VM.

Valid **e\_range** and **p\_range** formats include a number, number range, or comma-delimited list of numbers and ranges.

##### Example

This command displays the Vnics connected to **interface ethernet 24**.

```
switch> show vmtracer interface ethernet 24 vnic counters
Physical Intf: Ethernet24
Host: 10.17.28.8/site1/dvUplink1
VM Name vNic Input Pkt/Byte/% Output Pkt/Byte/%
vCenter1 Network adapter 2 2550/ 187175/ 0.6 6/ 360/ 0.0
vCenter2 Network adapter 2 418615/ 30678024/ 99.4 1904439/ 1145654613/100.0
Summary Summary 421165/ 30865199/100.0 1904445/ 1145654973/100.0 switch>
```

#### 21.6.4.13 show vmtracer vxlan segment

The **show vmtracer vxlan segment** command displays information about the VXLAN segments that are managed by the connected NSX for vSphere® (NSX-V).

##### Command Mode

EXEC

##### Command Syntax

```
show vmtracer segment ENTITY
```

##### Parameters

**ENTITY** specifies the information that the command displays. Options include:

- **no parameter** displays information for VXLAN segments.
- **pool** displays resource pools available to segments.
- **pool pool\_name** displays connection information about the specified pool.
- **range** displays the VNI range of the managed segments.

##### Examples

- This command displays the VXLAN segments managed by the NSX-V.

```
switch> show vmtracer vxlan segment
Name VNI Multicast IP Network Scope

Eng Wire 5002 237.0.0.1 abcde
HR Wire 5000 237.0.0.2 abcde switch>
```

- This command displays the resource pools available to the VXLANs.

```
switch> show vmtracer vxlan segment pool
Name Description Segments

abcde Spans Cluster 1 and Cluster 2 Eng Wire, HR Wire switch>
```

- This command displays connection and packet information for the **abcde** pool.

```
switch> show vmtracer vxlan segment pool abcde
Name: abcde
Description: Spans Cluster 1 and Cluster 2
Segments: Eng Wire, HR Wire

VXLAN Segment Cluster Host VTEP IP DVS VLAN MTU
Eng Wire Cluster2 test2.example.com 10.168.200.1/24 dvs-test2 200 1600
Eng Wire Cluster1 test2.example.com 10.168.100.1/24 dvs-test1 100 1600
HR Wire Cluster1 test2.example.com 10.168.100.1/24 dvs-test1 100 1600
HR Wire Cluster2 test2.example.com 10.168.200.1/24 dvs-test2 200 1600 switch>
```

- This command displays the VNI range of the VXLAN segments.

```
switch> show vmtracer vxlan segment range
VNI Range Multicast IP Range

5000 - 5024 237.0.0.1 - 237.0.0.117

Name VNI Multicast IP Network Scope

HR Wire 5002 237.0.0.1 abcde
Eng Wire 5000 237.0.0.2 abcde switch>
```

#### 21.6.4.14 show vmtracer vxlan vm

The **show vmtracer vxlan vm** command displays the VXLAN segments, their VTEP IP numbers, and their VM endpoints that are managed by the connected NSX for vSphere® (NSX-V).

##### Command Mode

EXEC

##### Command Syntax

```
show vmtracer vxlan vm
```

##### Example

This command displays the VM endpoints of the VXLAN segments managed by the NSX-V.

```
switch> show vmtracer vxlan vm
VXLAN Segment VTEP IP VLAN VMs
Eng Wire 192.168.200.1/24 200 Eng VM3, Eng VM2
Eng Wire 192.168.100.1/24 100 Eng VM1
HR Wire 192.168.100.1/24 100 HR VM2, HR VM1
HR Wire 192.168.200.1/24 200 --
switch>
```

#### 21.6.4.15 source-interface

The **source-interface** command allows you to connect to a remote vCenter endpoint by using the primary address of the interface as the source IP address. If the interface is not specified, the source IP address is determined by the routing table.

The **no source-interface** and **default source-interface** commands restore default behavior by removing the **source-interface** command from the **running-config**.

##### Command Mode

Vmtracer Configuration

##### Command Syntax

```
source-interface [INTERFACE_NAME]
no source-interface
default source-interface
```

##### Parameters

**INTERFACE\_NAME** specifies the interface for which the information is displayed. Options include:

- **Ethernet e\_num** specifies the Ethernet interface number.
- **Loopback l\_num** specifies the loopback interface number. Value ranges from **0** to **2100**.
- **Management m\_num** specifies the management interface number. The values are **1** or **2**.
- **Port-Channel {lag\_num | lag\_num.sub\_num}** specifies the port-channel interface number. Value of interface ranges from **1** to **2000**. Value of sub-interface ranges from **1** to **4094**.
- **Tunnel tunnel\_num** specifies the tunnel interface number. Value ranges from **1** to **255**.
- **UnconnectedEthernet port\_num** specifies the unconnected Ethernet port number. Value ranges from **1** to **8**.
- **VLAN vlan\_num** specifies the VLAN interface number. Value ranges from **1** to **4094**.

##### Related Commands

The [vmtracer session](#) command places the switch in the **vmtracer** configuration mode.

##### Examples

- This command configures VM Tracer to use **interface Ethernet 17** to derive the source address for session packets.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# source-interface Ethernet 17
switch(config-vmtracer-session-system_1)#{
```

- This command configures **interface Loopback 0** for VM Tracer session.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# source-interface Loopback 0
switch(config-vmtracer-session-system_1)#{
```

- This command configures **interface management 1** for VM Tracer session.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# source-interface management 1
switch(config-vmtracer-session-system_1)#{
```

- This command configures ***port-channel 10*** for VM Tracer session.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# source-interface port-channel 10
switch(config-vmtracer-session-system_1)#{
```

- This command configures ***interface tunnel 25*** for VM Tracer session.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# source-interface tunnel 25
switch(config-vmtracer-session-system_1)#{
```

- This command configures unconnected ***interface Ethernet 1*** for VM Tracer session.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# source-interface unconnected Ethernet 1
switch(config-vmtracer-session-system_1)#{
```

- This command configures ***interface vlan 25*** for VM Tracer session.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# source-interface vlan 25
switch(config-vmtracer-session-system_1)#{
```

---

#### 21.6.4.16 url (vmtracer mode)

The **url** command specifies the vCenter server location that is monitored by the session being edited by the current vmtracer mode. The command must reference a fully formed secure url.

##### Command Mode

Vmtracer Configuration

##### Command Syntax

**url** *url\_name*

##### Parameter

**url\_name** location of the vCenter server. Valid formats include IP address (dotted decimal notation) and fully qualified domain name.

##### Related Commands

The **vmtracer session** command places the switch in the **vmtracer** configuration mode.

##### Example

This command specifies the location of the vCenter monitored by the **system\_1** VM Tracer session.

```
switch(vmtracer-system_1) # url https://example.com/sdk
switch(vmtracer-system_1) #
```

## 21.6.4.17 url

The **url** command specifies the NSX for vSphere® (NSX-V) server location monitored for VXLAN information by the configuration mode VM Tracer session. The command must reference a fully formed secure URL.

The **url** statement is replaced in running-config for the configuration mode session by a subsequent **url** command. The statement is removed by deleting the NSX-V instance through a **vxlan** command in **vmtracer** configuration mode.

### Command Mode

Vmtracer-VXLAN Configuration

### Command Syntax

**url *url\_name***

### Parameter

**url\_name** location of the NSX-V server. Valid formats include IP address (dotted decimal notation) and fully qualified domain name.

### Related Commands

The **vxlan** command places the switch in the **vmtracer-vxlan** configuration mode.

### Example

This command configures the location of the NSX-V monitored by the **vnet-1** VM Tracer session.

```
switch(config)# vmtracer session vnet-1
switch(config-vmtracer-vnet-1)# vxlan
switch(config-vmtracer-vnet-1-vxlan)# url https://example.com/sdk
switch(config-vmtracer-vnet-1-vxlan)# exit
switch(config-vmtracer-vnet-1)# show active
vmtracer session vnet-1
 allowed-vlan 1-4094
 vxlan
 url https://example.com/sdk
switch(config-vmtracer-vnet-1)#

```

---

#### 21.6.4.18 username

The **username** command identifies the switch account name on the vCenter server. The switch uses this user name to access vCenter information.

##### Command Mode

Vmtracer Configuration

##### Command Syntax

`username name_string`

##### Parameter

***name\_string*** vCenter account user name. Parameter must match the user name configured on the vCenter.

##### Related Commands

The [vmtracer session](#) command places the switch in the **vmtracer** configuration mode.

##### Example

This command configures the user name for the vCenter associated with the **system\_1** session. The session uses this user name to log into the vCenter server.

```
switch(vmtracer-system_1) # username a-switch_01
switch(vmtracer-system_1) #
```

#### 21.6.4.19 username (vmtracer-vxlan mode)

The **username** command identifies the switch's account name on the NSX for vSphere® (NSX-V) server located at the URL configured for the configuration mode VM Tracer. The switch uses this user name to access NSX-V information.

The **username** statement is replaced in **running-config** for the configuration mode interface by a subsequent **username** command. The statement is removed by deleting the NSX-V instance through a **vxlan** command in the **vmtracer** configuration mode.

##### Command Mode

Vmtracer-VXLAN Configuration

##### Command Syntax

**username *name\_string***

##### Parameter

***name\_string*** NSX-V account user name. Parameter must match a user name configured on the NSX-V.

##### Related Commands

The **vxlan** command places the switch in the **vmtracer-vxlan** configuration mode.

##### Example

This command configures the user name of admin for the NSX-V located at the URL specified by the URL command.

```
switch(config)# vmtracer session vnet-1
switch(config-vmtracer-vnet-1)# vxlan
switch(config-vmtracer-vnet-1-vxlan)# url https://example.com/sdk
switch(config-vmtracer-vnet-1-vxlan)# username admin
switch(config-vmtracer-vnet-1-vxlan)# exit
switch(config-vmtracer-vnet-1)# show active
vmtracer session vnet-1
 allowed-vlan 1-4094
 vxlan
 url https://example.com/sdk
 username admin
switch(config-vmtracer-vnet-1) #
```

---

#### 21.6.4.20 vmtracer

The **vmtracer** command enables **vmtracer** mode on the configuration mode interface. Interfaces with vmtracer mode enabled send discovery packets to the connected vSwitch.

The **no vmtracer** and **default vmtracer** commands disable **vmtracer** mode on the configuration mode interface by removing the corresponding **vmtracer** command from **running-config**.

#### Command Mode

Interface-Ethernet Configuration Interface-Port-channel Configuration

#### Command Syntax

**vmtracer HOST\_TYPE**

**no vmtracer HOST\_TYPE**

**default vmtracer HOST\_TYPE**

#### Parameters

**HOST\_TYPE** - the type of hypervisor that controls the vSwitch to which the interface connects.

- **vmware-esx** - ESX or ESXI hypervisor (VMware).

#### Examples

- These commands enable the **vmtracer** mode on the **interface Ethernet 3**.

```
switch(config)# interface Ethernet 3
switch(config-if-Et3)# vmtracer vmware-esx
switch(config-if-Et3) #
```

- This command disables the **vmtracer** mode on the **interface Ethernet 3**.

```
switch(config-if-Et3)# no vmtracer vmware-esx
switch(config-if-Et3) #
```

#### 21.6.4.21 vmtracer session

The **vmtracer session** command places the switch in the **vmtracer** mode for the specified session. The command creates a new session or loads an existing session for editing.

A VM Tracer session connects the switch to a vCenter server at a specified location, then downloads data about VMs and vSwitches managed by ESX hosts connected to switch ports. The switch supports a maximum of four VM Tracer sessions.

Configure VM Tracer session parameters in the **vmtracer** mode. Parameters configured in the **vmtracer** mode include the vCenter location and dynamic VLAN usage.

The **no vmtracer session** and **default vmtracer session** commands disable the session and remove the configuration from **running-config**.

##### Command Mode

Global Configuration

##### Command Syntax

```
vmtracer session name
no vmtracer session name
default vmtracer session name
```

##### Parameter

**name** The label assigned to the VM Tracer session.

##### Examples

- This command enters **vmtracer** mode for the **system\_1** session.

```
switch(config)# vmtracer session system_1
switch(vmtracer-system_1) #
```

- This command disables the **system\_1** VM Tracer session. The **system\_1** session and removes all of the parameters from **running-config**

```
switch(config)#no vmtracer session system_1
switch(config) #
```

---

## 21.6.4.22 vrf

The **vrf** command allows the switch to communicate with a vCenter server by enabling VmTracer configuration mode. By default, VmTracer is enabled only in the **default vrf** command.

### Command Mode

Vmtracer Configuration

### Command Syntax

```
vrf vrf_name
```

### Parameter

**vrf\_name** specifies information of the corresponding VRF.

### Example

These commands place the VRF **vrf1** in the **vmtracer** configuration mode.

```
switch(config)# vmtracer session system_1
switch(config-vmtracer-session-system_1)# vrf vrf1
switch(config-vmtracer-session-system_1) #
```

---

## 21.6.4.23 vxlan

The **vxlan** command places the switch in the **vmtracer-vxlan** configuration mode. To monitor VXLAN based VMware configurations, the switch must communicate with a NSX for vSphere® (NSX-V). The **vmtracer-vxlan** configuration mode specifies the location and user account data that allows the switch to access a NSX-V within the configuration mode **vmtracer** session. Each VM Tracer session can be associated with one NSX-V instance.

The **no vxlan** and **default interface vxlan** commands delete the NSX-V instance from the configuration mode **vmtracer** session by removing all of the **vmtracer-vxlan** mode commands from **running-config**.

### Command Mode

Vmtracer Configuration

### Command Syntax

```
vxlan
no vxlan
default vxlan
```

### Related Command

The **vmtracer session** command places the switch in the **vmtracer** configuration mode.

### Example

These commands create the vShield instance for the VMTracer session named **vnet-1**.

```
switch(config)# vmtracer session vnet-1
switch(config-vmtracer-vnet-1)# vxlan
switch(config-vmtracer-vnet-1-vxlan) #
```

## 21.7 MapReduce Tracer

This section describes Arista's implementation of MapReduce Tracer, including configuration instructions and command descriptions. Topics covered by this section include the following:

- [MapReduce Tracer Introduction](#)
- [MapReduce Tracer Configuration](#)
- [Displaying MapReduce Tracer Results](#)
- [MapReduce Tracer Commands](#)

### 21.7.1 MapReduce Tracer Introduction

MapReduce Tracer provides a network tool that monitors Hadoop nodes directly connected to Arista switches. MapReduce Tracer requires the following parameters:

- Hadoop clusters deployed with a L3 design.
- The top of rack switch becomes the default gateway to all attached TaskTracker nodes.
- JobTracker RPC ports do not require authentication.
- Nodes cannot simultaneously belong to multiple Hadoop clusters.
- Access all TaskTrackers within a cluster through a common HTTP access port.
- The switch DNS or static host configuration facilitates TaskTracker name resolution.

Map Reduce Tracer supports these Hadoop releases:

- Apache 0.20.205
- Apache 1.2.1
- Cloudera 3u6
- Cloudera 4.1.3
- Cloudera 4.3.0
- HortonWorks 1.3
- Cloudera 4.5.0

These sections briefly describe Hadoop, Hadoop data structures, and MapReduce Tracer.

#### 21.7.1.1 Hadoop Description

Apache Hadoop is an open-source, Java-based software framework that supports large dataset storage and processing in a distributed computational environment. It is licensed under Apache License 2.0 and developed by a global community.

Hadoop facilitates application execution on systems comprising thousands of nodes utilizing petabytes of data. The distributed file system facilitates rapid data transfer among nodes and supports continued operations when individual nodes fail or become inaccessible.

Hadoop Distributed File System (HDFS) contains a distributed file system that stores data on the commodity machines to provide high aggregate bandwidth across the cluster.

---

### 21.7.1.2 Hadoop Cluster Structure

A cluster consists of a server group that functions as a single system to provide high availability through load balancing and parallel processing. A Hadoop cluster provides a type of computational cluster designed for storing and analyzing large amounts of unstructured data in a distributed computing environment.

Typical Hadoop clusters include one main node and multiple worker nodes. The main node consists of TaskTracker, JobTracker, NameNode, and DataNode functions. The worker nodes include a TaskTracker and DataNode.

### 21.7.1.3 Map Reduce

Hadoop implements a MapReduce algorithm to process large datasets by distributing parallel tasks to nodes within a cluster. The MapReduce program includes a Map procedure that filters data and a Reduce procedure that processes the data.

MapReduce manages task and data distribution to cluster nodes to execute tasks in parallel, and data transfers between cluster components support redundancy and fault tolerance.

The MapReduce engine comprises one JobTracker and multiple TaskTrackers nodes within the Hadoop cluster. The JobTracker receives MapReduce jobs from a client application and manages the completion of these jobs by submitting tasks to available TaskTracker nodes. If a TaskTracker fails to perform the assigned task, the JobTracker reschedules that part of the job to another node.

### 21.7.1.4 MapReduce Tracer Function

MapReduce Tracer allows you to track and interact with Hadoop nodes directly connected to Arista switches in a cluster. MapReduce Tracer communicates with a JobTracker to obtain a list of all nodes in a cluster. Then, it queries JobTracker and TaskTrackers for information regarding the running jobs and the progress of those jobs. This process creates a map of TaskTrackers with the types of jobs. Use **show** commands to display the data in tables using the CLI and EAPI.

MapReduce Tracer only monitors nodes directly connected to the switch on L3 networks. Directly connected nodes use the top-of-rack switch as the default gateway, and the switch learns ARP entries for these nodes. JobTracker filters nodes by tracking ARP entries to remove nodes not directly accessible and provides a list of nodes.

MapReduce Tracer creates a database of nodes from the filtered list. After creating the database, the switch queries the JobTracker and TaskTrackers to obtain the following:

- Number of monitored Hadoop nodes
- List of monitored nodes including IP addresses
- Running jobs by TaskTrackers
- JobTracker and TaskTracker statistics

MapReduce Tracer can simultaneously monitor multiple clusters. This means the directly connected TaskTracker nodes can belong to different clusters. EOS supports a maximum of five clusters per switch.

## 21.7.2 MapReduce Tracer Configuration

The **MapReduce Tracer** structures configuration commands into two configuration levels::

- Access the MapReduce Tracer Configuration Mode through the Global Configuration Mode and control the global MapReduce Tracer settings.
- Access the Monitor-Hadoop-Cluster Configuration Mode through the Monitor-Hadoop Configuration Mode and define polling configurations to monitor individual Hadoop clusters.

These sections describe MapReduce Tracer configuration processes:

- [Configuring MapReduce Tracer Globally](#)
- [Configuring Hadoop Cluster Access](#)
- [MapReduce Tracer Example](#)

MapReduce Tracer functions after enabling it globally. Each polling configuration can be enabled after enabling the feature.

### 21.7.2.1 Configuring MapReduce Tracer Globally

Configure the MapReduce Tracer global parameters in the Monitor-Hadoop Configuration Mode. Tasks performed in this mode include specifying connection parameters to Hadoop clusters and globally enabling MapReduce Tracer.

#### Accessing the Monitor-Hadoop Configuration Mode

Access the Monitor-Hadoop Configuration Mode using the [monitor hadoop](#) command. Monitor-Hadoop Configuration Mode does not apply group changes. The ***running-config*** immediately stores the statements when entered. The ***exit*** command returns the switch to Global Configuration mode.

#### Examples

- Use the following commands to place the switch in the Monitor-Hadoop Configuration Mode.

```
switch(config)#monitor hadoop
switch(config-monitor-hadoop) #
```

- This command exits the Monitor-Hadoop Configuration Mode.

```
switch(config-monitor-hadoop) # exit
switch(config) #
```

- This command deletes all previously configured Monitor-Hadoop Configuration Mode commands.

```
switch(config) # no monitor hadoop
switch(config) #
```

#### Enabling MapReduce Tracer Globally

Globally enable MapReduce Tracer using the **no** version of the [shutdown \(Monitor-Hadoop\)](#) command. EOS globally disables MapReduce Tracer by default.

#### Example

These commands globally enable MapReduce Tracer.

```
switch(config) # monitor hadoop
switch(config-monitor-hadoop) # no shutdown
switch(config-monitor-hadoop) # show active
 monitor hadoop
 no shutdown
switch(config-monitor-hadoop) #
```

#### Creating a Cluster Monitor

Create a cluster monitor by accessing the Monitor-Hadoop-Cluster Configuration Mode mode with the [cluster \(Monitor Hadoop\)](#) command. Each monitor has a cluster ID and probes one Hadoop cluster. When the command specifies a monitor with a previously defined cluster ID, subsequent commands edit the monitor

---

parameters. Create a new monitor with a new cluster ID by entering a command that specifies a nonexistent cluster ID.

### Example

Use the following commands to enter the Monitor-Hadoop-Cluster Configuration Mode to edit a cluster monitor with the cluster-id, **CL2**:

```
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
switch(config-monitor-hadoop-CL2) #
```

## 21.7.2.2 Configuring Hadoop Cluster Access

Configure cluster monitors in the Monitor-Hadoop-Cluster Configuration Mode. Each monitor corresponds to a Hadoop cluster with the following configurable parameters:

- JobTracker access parameters including the IP address, port number, and username
- TaskTracker access port
- Polling interval
- Cluster description
- Enabled setting

The minimum explicit configuration includes the JobTracker address and username. Use the default values for all other parameters. By default, cluster monitors are disabled.

The [cluster \(Monitor Hadoop\)](#) command places the switch in the Monitor-Hadoop-Cluster Configuration Mode for the specified monitor with a cluster connection parameters.

Enable a cluster monitor by using the **no** version of the [shutdown \(Monitor-Hadoop\)](#) command when enabling MapReduce Tracer globally.

### 21.7.2.2.1 Configuring JobTracker

A cluster JobTracker resides on the master node and schedules work for the cluster TaskTracker nodes. The [jobtracker \(Monitor Hadoop Cluster\)](#) command specifies connection parameters to the monitored cluster.

JobTracker parameters include the node location as an IPv4 address or hostname, RPC port, and username. The default RPC port is **8021**. Location and username parameters do not have default values and must be explicitly configured.

### Example

For the **CL2** monitor, these commands configure connection parameters to a JobTracker node at **10.4.4.4** with the username **account1**.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# jobtracker host 10.4.4.4 username account1
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
 jobtracker host 10.4.4.4 user account1
switch(config-monitor-hadoop-CL2) #
```

### 21.7.2.2.2 TaskTracker Configuration

The [tasktracker \(Monitor Hadoop Cluster\)](#) command specifies the HTTP port that accesses the TaskTrackers for the Hadoop cluster probed by the Configuration Mode Monitor. The switch compiles a list of the cluster TaskTracker addresses by periodically polling the cluster JobTracker.

The TaskTracker HTTP port uses **50060** by default.

#### Examples

- For the **CL2** monitor, use the following commands to configure a TaskTracker access port of **51000**.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# tasktracker http-port 51000
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
 tasktracker http-port 51000
switch(config-monitor-hadoop-CL2) #
```

- Use the following commands to restore the default TaskTracker HTTP access port address of **50060**.

```
switch(config-monitor-hadoop-CL2)# no tasktracker http-port
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
switch(config-monitor-hadoop-CL2)# show active all
monitor hadoop
 cluster CL2
 jobtracker rpc-port 8021
 tasktracker http-port 50060
 interval 10
 shutdown
switch(config-monitor-hadoop-CL2) #
```

### 21.7.2.2.3 Configuring Polling Intervals

After completing the Hadoop Monitor configuration, the switch polls the cluster JobTracker to maintain the list of active TaskTracker nodes associated with the monitored cluster and compile Hadoop job statistics. The [interval \(Monitor Hadoop Cluster\)](#) command specifies the interval between polls to the JobTracker of the monitored cluster. By default, the switch uses a polling interval of **10** seconds.

#### Example

This command sets the JobTracker polling interval to **25** seconds for the cluster monitored by the **CL2** MapReduce Tracer configuration.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# interval 25
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
 interval 25
switch(config-monitor-hadoop-CL2) #
```

### 21.7.2.3 MapReduce Tracer Example

Use the following commands to create monitors that probe two Hadoop clusters, enables each monitor individually, then enables MapReduce Tracer globally. Monitor parameters for the clusters include the following:

---

### **Cluster ID CL\_1**

- Jobtracker
  - IP address - **10.15.2.2**
  - RPC port - **8021**
  - username - **xyz1**
- TaskTracker
  - HTTP address - **54000**
- JobTracker
  - Polling Interval - **10** seconds (default)

### **Cluster ID CL\_2**

- Jobtracker
  - IP address - **10.21.5.2**
  - RPC port - **9521**
  - username - **qrst**
- TaskTracker
  - HTTP address - **500060**
- JobTracker Polling Interval
  - Polling Interval - **5** seconds (default)

### **Example**

```
switch(config)#monitor hadoop
switch(config-monitor-hadoop)#cluster CL_1

switch(config-monitor-hadoop-CL_1)#jobtracker host 10.15.2.2 username xyz1
switch(config-monitor-hadoop-CL_1)#tasktracker http-port 54000
switch(config-monitor-hadoop-CL_1)#no shutdown
switch(config-monitor-hadoop-CL_1)#exit

switch(config-monitor-hadoop)#cluster CL_2
switch(config-monitor-hadoop-CL_2)#jobtracker host 10.21.5.2 rpc-port 9521
switch(config-monitor-hadoop-CL_2)#interval 5
switch(config-monitor-hadoop-CL_2)#no shutdown
switch(config-monitor-hadoop-CL_2)#exit

switch(config-monitor-hadoop)#no shutdown
switch(config-monitor-hadoop)#show active
monitor hadoop
 no shutdown
 cluster CL_1
 jobtracker host 10.15.2.2 user xyz1
 tasktracker http-port 54000
 no shutdown
 !
 cluster CL_2
 jobtracker host 10.21.5.2 rpc-port 9521 user qrst4
 interval 5
 no shutdown

switch(config-monitor-hadoop)#show active all
monitor hadoop
 no shutdown
 cluster CL_1
 jobtracker host 10.15.2.2 rpc-port 8021 user xyz1
 tasktracker http-port 54000
 interval 10
 no shutdown
 !
```

```

cluster CL_2
 jobtracker host 10.21.5.2 rpc-port 9521 user qrst4
 tasktracker http-port 50060
 interval 5
 no shutdown
switch(config-monitor-hadoop)#exit
switch(config)#

```

## 21.7.3 Displaying MapReduce Tracer Results

MapReduce Tracer display commands provide information about the configuration and activity on the monitored clusters.

This section contains the following topics:

- [Displaying MapReduce Tracer Status](#)
- [Displaying the Cluster Configuration and Connections](#)
- [Displaying Job Lists Information](#)
- [Displaying Job Data](#)
- [Displaying TaskTracker Lists](#)
- [Displaying TaskTracker Connection and Activity](#)
- [Displaying Data Bursts](#)
- [Low-memory Mode Overview](#)

### 21.7.3.1 Displaying MapReduce Tracer Status

Display the MapReduce Tracer status through the [show monitor hadoop status](#) command. Status information includes the enabled status and the number of monitored clusters, TaskTrackers, and locally running jobs.

#### Example

This command displays MapReduce Tracer status for all connected clusters and TaskTrackers.

```

switch> show monitor hadoop status

Last updated: 2013-10-06 18:14:23
Mapreduce Tracer status:
 Admin status : Enabled
 Operational status : Enabled
 Number of clusters configured : 3
 Number of local TaskTrackers : 4
 Number of jobs running locally : 4 switch>

```

### 21.7.3.2 Displaying the Cluster Configuration and Connections

Use the following cluster configuration and connection information commands to display information about the configurations and connections:

- [show monitor hadoop cluster all](#) - Displays configuration and connection data for all monitored clusters.
- [show monitor hadoop cluster status](#) - Displays configuration and connection data for a specified cluster.
- [show monitor hadoop tasktracker status](#) - Displays connection and activity information for TaskTrackers in a specified cluster, on a specified node, or accessed through a specified interface.

#### Example

---

Use the following command to display configuration and connection data for the **Cluster0** cluster.

```
switch>show monitor hadoop cluster Cluster0 status

Last updated: 2013-10-06 18:14:23
Cluster status for cluster: Cluster0
 Admin status : Enabled
 JobTracker host : host0
 JobTracker RPC port : 9000
 JobTracker user : user0
 JobTracker polling interval : 100 seconds
 TaskTracker HTTP port : 8800
 Operational status : Enabled
 Active TaskTrackers : 31
 Blacklisted TaskTrackers : 1
 Decommissioned TaskTrackers : 1
 Tracker expiry interval : 20.0
 Map slots (used/total) : 10/100
 Reduce slots (used/total) : 11/110
 JobTracker heap size : 1.04GB (max: 2.08GB)

switch>
```

### 21.7.3.3 Displaying Job Lists Information

The following commands display rosters of currently running job or previously ran jobs:

- [show monitor hadoop](#) - Jobs running on all monitored Hadoop clusters.
- [show monitor hadoop cluster counters](#) - Jobs running on a specified cluster and byte counter data.
- [show monitor hadoop cluster history](#) - Jobs previously run on a specified cluster.
  - [clear monitor hadoop job-history](#) - Includes jobs that ran since enabling the monitor, reloading the switch, or clearing the job history.
- [show monitor hadoop cluster jobs](#) - Jobs running on a specified cluster.
- [show monitor hadoop history](#) - Jobs that ran on all configured clusters is accessed through.
  - [clear monitor hadoop job-history](#) - Includes jobs that ran since enabling the monitor, reloading the switch, or clearing the job history.
- [show monitor hadoop tasktracker counters](#): Jobs running on a specified TaskTracker and byte counter data.

### Examples

- Use the following command to display the jobs running on all monitored clusters.

```
switch> show monitor hadoop

Last updated: 2013-10-06 18:14:23
Currently running jobs: 4
JobID Job Name Cluster Maps (#/%) Reduces (#/%) Start Time
----- -----
1 ReallyAVeryLon\
gNameForJob1 Cluster0 2/12.34% 0/13.45% 2013-10-06 17:56:03
2 ShortName2 Cluster0 2/24.68% 0/26.90% 2013-10-06 17:37:43
510001 ReallyAVeryLon\

510002 ShortName12 Cluster1 2/24.68% 0/26.90% 2013-10-06 17:37:43
switch>
```

- Use the following command to display data for the previously run jobs on connected Hadoop clusters.

```
switch> show monitor hadoop history

Job history for all clusters:
JobID Job Name Cluster Start Time End Time Bytes In Bytes Out
----- -----
2 AReallyBigHist\
oricalJobName Cluster0 2013-10-06 17:41:03 06:47:43 26.08GB 13.04GB
442 AReallyBigHist\
Cluster1 2013-10-06 2013-10-09 26.08GB 13.04GB
```

```

442 oricalJobName 17:41:03 06:47:43
 AReallyBigHist\ Cluster1 2013-10-06 2013-10-09 26.08GB 13.04GB
2 oricalJobName 17:41:03 06:47:43
 AReallyBigHist\ Cluster0 2013-10-06 2013-10-09 26.08GB 13.04GB

 HistoryJob1 Cluster1 2013-10-06 2013-10-08 26.08GB 13.04GB
1 HistoryJob1 Cluster0 2013-10-06 2013-10-08 26.08GB 13.04GB
1 HistoryJob1 Cluster0 17:57:43 00:31:03
1 HistoryJob1 Cluster0 17:57:43 00:31:03 switch>

```

- Use the following command to display jobs running on cluster **Cluster0** and byte counters for each job.

```

switch> show monitor hadoop cluster Cluster0 counters

Last updated: 2013-10-06 18:14:23
Counters for currently running jobs on cluster: Cluster0
----- JobId Job Name User Bytes In Bytes Out Start Time -----
2 ShortName2 JobUser2 37.36GB 76.29MB 2013-10-06 17:37:43
1 ReallyAVeryLon\ JobUser1 37.36GB 76.29MB 2013-10-06 17:56:03
gNameForAJob1 switch>

```

#### 21.7.3.4 Displaying Job Data

The following commands display information about active jobs or previously active jobs on monitored clusters. Available data includes Job Identifiers, JobTracker ID, Job start time, Job stop time, data consumption, and progress statistics.

- [show monitor hadoop cluster history jobs](#) - Data consumption, start and stop times, and JobTracker ID for a specific job.
- [show monitor hadoop cluster jobs <job number>](#) - Data consumption, start and stop times, priority, JobTracker ID, and progress statistics for a specified job.
- [show monitor hadoop cluster jobs counter](#) - HDFS (Hadoop Distributed File System) data consumption and and shuffle byte counters for a specified job.
- [show monitor hadoop counters](#) - Data through and start time for jobs running on all monitored clusters.
- [show monitor hadoop tasktracker jobs](#) - Progress statistics and start times are available for jobs running on specified TaskTracker.
- [show monitor hadoop tasktracker running-tasks](#) - Job progress and byte counts of jobs running on a specified Hadoop cluster .
- [show monitor hadoop tasktracker running-tasks cluster job task](#) - Progress statistics, HDFS data consumption, start time, and progress information for the specified task of a running job.
- [show monitor hadoop tasktracker counters](#) - Data consumption and start times for jobs running on a specified TaskTracker.

#### Examples

- Use the following command to display information about **job 1** on cluster **Cluster0**.

```

switch> show monitor hadoop cluster Cluster0 history job 1

Job history data for job: HistoryJob1
 Cluster : Cluster0
 Job Id : 1
 JT Id : 201310110013
 User : HistoryUser1
 Job start time : 2013-10-06 17:57:43
 Job end time : 2013-10-08 00:31:03

 Per Interface job counters:
 Interface TaskTracker Bytes In Bytes Out
 ----- -----
 Ethernet7 TaskTracker2 26.08GB 13.04GB switch>

```

- Use the following command to display information about **job 1** running on cluster **Cluster0**.

```
switch> show monitor hadoop cluster Cluster0 jobs 1

Last updated: 2013-10-06 18:14:23
Information for job: ReallyAVeryLongNameForAJob1 running on cluster: Cluster0
 Cluster : Cluster0
 Id : 1
 Name : ReallyAVeryLongNameForAJob1
 User : JobUser1
 Priority : veryHigh
 Running state : running
 Number of map tasks : 2
 Number of reduce tasks : 0
 Start time : 2013-10-06 17:56:03
 Bytes In : 37.36GB
 Bytes Out : 76.29MB
 Map Progress : 12.34%
 Reduce Progress : 13.45%
 Cleanup Progress : 14.56%
 Setup Progress : 15.67%

switch>
```

- Use the following command to display data for jobs running on **TaskTracker1**.

```
switch> show monitor hadoop tasktracker host TaskTracker1 jobs

Last updated: 2013-10-06 18:14:23
Running job for TaskTracker: TaskTracker1
JobId Job Name Cluster Maps(#/%) Reduces(#/%) Start Time
----- -----
1 ReallyAVeryLon\ Cluster0 2/12.34% 0/13.45% 2013-10-06 17:56:03
 gNameForAJob1
2 ShortName2 Cluster0 2/24.68% 0/26.90% 2013-10-06 17:37:43
switch>
```

### 21.7.3.5 Displaying TaskTracker Lists

These commands display lists of active TaskTrackers on monitored clusters:

- [show monitor hadoop cluster tasktracker](#) - TaskTrackers on a specified cluster.
- [show monitor hadoop tasktracker all](#) - TaskTrackers on all monitored clusters.

#### Example

Use the following command to display the TaskTrackers on the **Cluster0** cluster.

```
switch> show monitor hadoop cluster Cluster0 tasktracker

Last updated: 2013-10-06 18:14:23
Total 2 TaskTrackers on cluster Cluster0:
Node IP Address Interface Maps Reduces
----- -----
TaskTracker1 10.100.0.1 Ethernet7 4 0
TaskTracker2 10.100.0.2 Port-Channel7 4 0
switch>
```

### 21.7.3.6 Displaying TaskTracker Connection and Activity

Use the following TaskTracker commands to display connection and activity data:

- [show monitor hadoop tasktracker status](#) - Connection and activity information for TaskTrackers on a specified cluster or accessed through a specified interface.
- [show monitor hadoop tasktracker all counters](#) - Data consumption for TaskTrackers connected to monitored clusters.

## Example

Use the following command to display connection and activity data for TaskTracker on the **TaskTracker1** node.

```
switch> show monitor hadoop tasktracker host TaskTracker1 status
Last updated: 2013-10-06 18:14:23
 TaskTracker : TaskTracker1
 IP Address : 10.100.0.1
 Interface : Ethernet7
 State : active
 Running jobs : 2
 Running tasks : 4
 Map Tasks : 4
 Reduce Tasks : 0
 Total bytes read : 2.08GB
 Total bytes written : 4.24MB switch>
```

### 21.7.3.7 Displaying Data Bursts

The [show monitor hadoop traffic burst](#) command displays the largest data bursts for jobs running on a specified cluster or accessed through a specified node or interface. A data burst represents the data consumed during a polling interval.

## Example

Use the following command to display traffic burst data for all running jobs that are accessible through **port channel interface 7**.

```
switch> show monitor hadoop traffic burst interface Port-Channel 7
Last updated: 2013-10-06 18:14:23
Bursts on Interface: 'Port-Channel7' in cluster: Cluster0
Top 2 input bursts:
JobId Job Name Burst Time

 1 ShortName 3.07GB 2013-10-06 17:57:43
 2 ReallyAVeryLon\
 gNameForAJob 6.15GB 2013-10-06 17:41:03

Top 2 output bursts:
JobId Job Name Burst Time

 1 ShortName 4.10GB 2013-10-06 17:55:13
 2 ReallyAVeryLon\
 gNameForAJob 8.20GB 2013-10-06 17:36:03
```

### 21.7.3.8 Low-memory Mode Overview

Switch behavior can be improved using the **memory exhaustion** command when the switch gets low on available memory. Several factors can cause the low-memory or Out-of-Memory (OOM) state, including the following:

- Memory leaks in EOS or customer user processes.
- Process leaks due to multiple processes or scripts running at one time.
- Over configuration of the system that requires more memory than available.
- A large number of temporary (tmpfs) files such as logs.
- A large number of CLI sessions.
- Any event or agents that can consume more memory than available in the system.

---

Once the switch reaches the low-memory state, the system uses the **oom\_score**, which depends on the value of the **oom\_score\_adj** parameter to kill processes and free up available memory. The value for the parameter ranges from **-1000** (not shut down) to **1000** (shut down first) during an OOM state. Non-essential agents are assigned **oom\_score\_adj** values of **900** or greater.

When enabled, the system implements the following processes:

- Non-essential agents shut down by Linux do not restart.
- CLI restarts, and sends a message, "Restarting CLI due to memory exhaustion on the system", to all login sessions in the switch.
- Disables CLI Scheduler.

The system requires manual intervention through **reset system memory exhaustion** command to exit the mode and restart the agents.

## Configuring Low-memory Mode

The following examples apply to all platforms.

### Examples

- These commands configure the low-memory mode.

```
switch(config)# monitor system
switch(config-monitor-system)# memory exhaustion
switch(config-monitor-system-memory)# action agent non-critical hold-down
```

- The following command disables low-memory mode in **config-monitor-system-memory**.

```
switch(config-monitor-system-memory)# no action agent non-critical hold-down
```

- The following command exits low-memory mode after an OOM event has occurred and agents have been shut down. The command restarts the agents being held down and reenables the CLI scheduler.

```
switch(config-monitor)#reset system memory exhaustion
```

The **show monitor system** command shows the state of the system with the following information:

- Feature enabled.
- Low-memory mode (feature enabled and system experiencing OOM).
- Number of times the system entered low-memory mode.
- Last time the system entered low-memory mode (if applicable).
- Last time the system exited low-memory mode (if applicable).

### Example

```
switch#show monitor system
```

The following output displays on a system with the feature disabled and the system never entered the low-memory mode.

```
Memory Exhaustion Feature enabled: False
System currently in Memory Exhaustion: False
Number of times system entered Memory Exhaustion:
```

The following output displays on a system with the feature enabled and the system never entered the low-memory mode.

```
Memory Exhaustion Feature enabled: True
```

```
System currently in Memory Exhaustion: False
Number of times system entered Memory Exhaustion: 0
```

The following output displays on a system with the feature enabled and the system enters the low-memory mode.

```
Memory Exhaustion Feature enabled: True
System currently in Memory Exhaustion: True
Number of times system entered Memory Exhaustion: 1
Last time entered in Memory Exhaustion: 0:00:07 ago
```

The following output displays on a system with the feature enabled and the system enters the low-memory mode once, and has exited the low-memory mode.

```
Memory Exhaustion Feature enabled: True
System currently in Memory Exhaustion: False
Number of times system entered Memory Exhaustion: 1
Last time entered in Memory Exhaustion: 0:01:00 ago
Last time exited from Memory Exhaustion: 0:00:05 ago
```

### Configuring **oom\_score\_adj** for a daemon agent

To configure the **oom\_score\_adj** of any configured daemon, use the following command:

```
switch(config-daemon-<daemon_name>) # oom score adjustment <score>
```

**Note:** Similar to change the daemon heartbeat value, the new **oom\_score\_adj** value for the daemon is in effect after restarting the daemon by using **shutdown** command followed by a **no shutdown** command.

```
switch(config) # daemon daemonName
switch(config-daemon-daemonName) # oom score adjustment -200
switch(config-daemon-daemonName) # shutdown
switch(config-daemon-daemonName) # no shutdown
```

---

## 21.7.4 MapReduce Tracer Commands

### Global Configuration Commands

- monitor.hadoop

### Clear Hadoop Monitor Commands

- clear.monitor.hadoop.burst-counters
- clear.monitor.hadoop.job-history

### Display Commands

- show.agent.oom.scores
- show.monitor.hadoop
- show.monitor.hadoop.cluster.all
- show.monitor.hadoop.cluster.counters
- show.monitor.hadoop.cluster.history
- show.monitor.hadoop.cluster.history.jobs
- show.monitor.hadoop.cluster.jobs
- show.monitor.hadoop.cluster.jobs.<job.number>
- show.monitor.hadoop.cluster.jobs.counter
- show.monitor.hadoop.cluster.status
- show.monitor.hadoop.cluster.tasktracker
- show.monitor.hadoop.counters
- show.monitor.hadoop.history
- show.monitor.hadoop.status
- show.monitor.hadoop.tasktracker.all
- show.monitor.hadoop.tasktracker.all.counters
- show.monitor.hadoop.tasktracker.counters
- show.monitor.hadoop.tasktracker.jobs
- show.monitor.hadoop.tasktracker.running-tasks
- show.monitor.hadoop.tasktracker.running-tasks.cluster.job.task
- show.monitor.hadoop.tasktracker.status
- show.monitor.hadoop.traffic.burst
- show.monitor.system

### Hadoop Commands

- cluster (Monitor Hadoop)
- shutdown (Monitor-Hadoop)

### Hadoop-Cluster Commands

- description (Monitor Hadoop Cluster)
- interval (Monitor Hadoop Cluster)
- jobtracker (Monitor Hadoop Cluster)
- shutdown (Monitor Hadoop Cluster)
- tasktracker (Monitor Hadoop Cluster)

#### 21.7.4.1 clear monitor hadoop burst-counters

The **clear monitor hadoop burst-counters** command resets MapReduce Tracer burst counters for all jobs running on specified clusters.

##### Command Mode

Privileged EXEC

##### Command Syntax

```
clear monitor hadoop burst-counters [clusters]
```

##### Parameters

- ***clusters*** Hadoop clusters for which command displays data. Options include:
  - **no parameter** All clusters.
  - **cluster *c\_name*** Cluster name.

##### Example

This command clears the burst counters for all jobs running on **CL2** cluster.

```
switch# clear monitor hadoop burst-counters cluster CL2
Cleared burst counters switch#
```

---

#### 21.7.4.2 clear monitor hadoop job-history

The `clear monitor hadoop job-history` command resets the job history database for all specified clusters.

##### Command Mode

Privileged EXEC

##### Command Syntax

```
clear monitor hadoop job-history [clusters]
```

##### Parameters

- ***clusters*** Hadoop clusters for which command displays data. Options include:
  - **no parameter** All clusters.
  - **cluster *c\_name*** Cluster name.

##### Example

This command clears the job history on the **CL2** cluster.

```
switch# clear monitor hadoop job-history cluster CL2
Cleared job history switch#
```

### 21.7.4.3 cluster (Monitor Hadoop)

The **cluster** command is a monitor-hadoop command that places the switch in the ***monitor-hadoop-cluster mode*** for configuring and enabling a MapReduce Tracer monitor for a Hadoop cluster. The command either accesses an existing monitor configuration or creates a monitor.

The Monitor-Hadoop-Cluster Configuration Mode is not a group change mode. The ***running-config*** changes immediately after entering commands. Exiting the ***monitor-hadoop-cluster*** mode does not affect ***running-config***. The **exit** command returns the switch to the ***monitor-hadoop*** configuration mode.

The Configuration Mode Monitor is enabled by the **no** version of the [shutdown \(Monitor Hadoop Cluster\)](#). Enabling a monitor also requires that MapReduce Tracer is globally enabled ([shutdown \(Monitor Hadoop Cluster\)](#)).

The **no cluster** and **default cluster** commands remove the specified Hadoop cluster configuration from ***running-config***.

#### Command Mode

Monitor-Hadoop Configuration

#### Command Syntax

```
cluster cluster_name
no cluster cluster_name
default cluster cluster_name
```

#### Parameter

***cluster\_name*** Hadoop cluster name.

#### Related Command

The [monitor hadoop](#) command places the switch in the ***monitor-hadoop*** configuration mode.

#### Commands Available in Monitor-hadoop-cluster Configuration Mode

- [description \(Monitor Hadoop Cluster\)](#)
- [interval \(Monitor Hadoop Cluster\)](#)
- [jobtracker \(Monitor Hadoop Cluster\)](#)
- [shutdown \(Monitor Hadoop Cluster\)](#)
- [tasktracker \(Monitor Hadoop Cluster\)](#)

#### Examples

- These commands create the CL2 monitor and enters the ***monitor-hadoop-cluster*** mode for the monitor.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# show active
 monitor hadoop
 cluster CL2
switch(config-monitor-hadoop-CL2) #
```

- These commands exit the ***monitor-hadoop-cluster*** mode.

```
switch(config-monitor-hadoop-CL2) # exit
switch(config-monitor-hadoop) # show active
 monitor hadoop
 cluster CL2
switch(config-monitor-hadoop) #
```

- 
- These commands remove the CL2 monitor.

```
switch(config-monitor-hadoop)# no cluster CL2
switch(config-monitor-hadoop)# show active
switch(config-monitor-hadoop)#{
```

#### 21.7.4.4 description (Monitor Hadoop Cluster)

The **description** command adds a text string to the configuration mode MapReduce Tracer cluster monitor. The string has no functional impact on the monitor.

The **no description** and **default description** commands remove the text string from the configuration mode monitor by removing the corresponding **description** command from *running-config*.

##### Command Mode

Monitor-hadoop-cluster Configuration

##### Command Syntax

**description** *label\_text*

**no description**

**default description**

##### Parameter

***label\_text*** Character string assigned to the monitor configuration.

##### Related Command

The [cluster \(Monitor Hadoop\)](#) command places the switch in the **monitor-hadoop-cluster** configuration mode.

##### Example

These commands add description text to the **CL2** monitor.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# description First Cluster
monitor hadoop
 cluster CL2
 description First Cluster
 jobtracker host 10.3.3.3 user JANE
switch(config-monitor-hadoop-CL2)#{/pre}
```

---

#### 21.7.4.5 interval (Monitor Hadoop Cluster)

The **interval** command specifies the polling interval between queries to the Hadoop cluster JobTracker specified by configuration mode statements. The switch polls a cluster's JobTracker to update its list of active TaskTracker nodes and the statistics of jobs running in the cluster. This command controls the frequency of these polls. The default interval is **10** seconds.

The **no interval** and **default interval** commands restore the default interval of **10** seconds by removing the **interval** command from **running-config**.

#### Command Mode

Monitor-Hadoop Configuration

#### Command Syntax

```
interval period
no interval
default interval
```

#### Parameter

**period** Interval (seconds) between JobTracker polls. Value ranges from **1** to **600**. Default is **10**.

#### Related Commands

The [cluster \(Monitor Hadoop\)](#) command places the switch in the Monitor-Hadoop Configuration Mode.

#### Example

This command sets the JobTracker polling interval to **25** seconds for the **CL2** cluster configuration.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# interval 25
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
 interval 25
switch(config-monitor-hadoop-CL2) #
```

#### 21.7.4.6 jobtracker (Monitor Hadoop Cluster)

The **jobtracker** command specifies JobTracker access parameters for the cluster monitored by configuration mode monitor statements. A cluster's JobTracker is located on the master node and schedules work to the cluster's TaskTracker nodes.

Parameters required to communicate with a JobTracker include its node location (IPv4 address or hostname), RPC port, and username. The default RPC port is **8021**. Location and username parameters do not have default values and must be explicitly configured. A JobTracker command that specifies a partial parameter list modifies the existing corresponding **jobtracker** statement in **running-config**.

The **no jobtracker** and **default jobtracker** commands perform the following:

- removes the **jobtracker** statement from **running config** when it lists all command parameters.
- modifies the existing **jobtracker** statement when it lists a subset of command parameters.

#### Command Mode

Monitor-Hadoop-Cluster Configuration

#### Command Syntax

```
jobtracker [location][port][user]
no jobtracker[location][port][user]
default jobtracker [location][port][user]
```

All parameters may be placed in any order.

#### Parameters

- location** Address or hostname of JobTracker node. Options include:
  - no parameter** Location remains undefined or unchanged from a previous configuration.
  - host ipv4\_addr** IPv4 address of master (JobTracker) node.
  - host hostname** Hostname of master (JobTracker) node.
- port** JobTracker RPC port number. Default value is **8021**. Options include:
  - no parameter** Port number remains unchanged from previous configuration.
  - rdp-port port\_num** Port number of master (JobTracker) node. Value ranges from **1** to **65535**.
- user** Username that accesses JobTracker node. Options include:
  - no parameter** Username remains undefined or unchanged from previous configuration.
  - username name\_string** JobTracker username.

#### Related Command

The [cluster \(Monitor Hadoop\)](#) command places the switch in the Monitor-Hadoop-Cluster Configuration Mode.

#### Examples

- For the CL2 cluster configuration, these commands establish a connection to the JobTracker node at **10.4.4.4** with the username **account1**. The default RPC port (**8021**) is implicitly specified.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# jobtracker host 10.4.4.4 username account1
switch(config-monitor-hadoop-CL2)# show active

monitor hadoop
 cluster CL2
```

---

```
jobtracker host 10.4.4.4 user account1
switch(config-monitor-hadoop-CL2) #
```

- These commands modify the JobTracker configuration to specify an RPC port of **9000**.

```
switch(config-monitor-hadoop-CL2) # jobtracker rpc-port 9000
switch(config-monitor-hadoop-CL2) # show active

monitor hadoop
 cluster CL2
 jobtracker host 10.4.4.4 rpc-port 9000 user account1
switch(config-monitor-hadoop-CL2) #
```

#### 21.7.4.7 monitor hadoop

The **monitor hadoop** command places the switch in the Monitor-Hadoop Configuration Mode for configuring MapReduce Tracer monitors. A MapReduce Tracer monitor interacts with Hadoop cluster nodes directly attached to the switch. Tasks that the switch can perform through this interaction include the following:

- Compile a list of nodes in the cluster.
- Compile a list of jobs the nodes are running.
- Download progress of the running jobs.

The Monitor-Hadoop Configuration Mode is not a group change mode, and the ***running-config*** changes immediately upon entering commands. Exiting the Monitor-Hadoop Configuration Mode does not affect the ***running-config***. The **exit** command returns the switch to the Global configuration mode. MapReduce Tracer is enabled in the **monitor-hadoop** mode through the **no** version of the [shutdown \(Monitor Hadoop Cluster\)](#) command.

The **no monitor hadoop** and **default monitor hadoop** commands delete previously configured **monitor hadoop mode** configuration commands.

##### Command Mode

Global Configuration

##### Command Syntax

```
monitor hadoop
no monitor hadoop
default monitor hadoop
```

##### Commands Available in Monitor-hadoop Configuration Mode

- [cluster \(Monitor Hadoop\)](#)
- [shutdown \(Monitor Hadoop Cluster\)](#)

##### Examples

- These commands place the switch in the **monitor-hadoop** configuration mode.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)#End
```

- This command exits the **monitor-hadoop** mode.

```
switch(config-monitor-hadoop)# exit
switch(config)#
```

- This command deletes all previously configured **monitor-hadoop** configuration mode commands.

```
switch(config)# no monitor hadoop
switch(config)#
```

#### 21.7.4.8 show agent oom scores

The **show agent oom scores** command displays information for each agent if specified.

##### Command Mode

EXEC

---

## Command Syntax

```
show agent [agentName] oom scores
```

### Parameters

- **Display Values**

- **Agent name** Name(s) of agent(s) - processes.
- **RssAnon** Size of the resident anonymous memory for the given process.
- **VmSize** Current total virtual memory size for the process.
- **Max VmSize** Peak value of total virtual memory for the process.
- **oom\_score** Parameter used in determining which process to hold down.
- **oom\_score\_adj** Parameter used to adjust **oom\_score**.

### Example

This command displays the information for SNMP and Sysdb.

```
switch# show agent Snmp Sysdb oom scores
Agent Name RssAnon VmSize Max VmSize oom_score oom_score_adj
----- -----
Snmp 34.8MB 536.1MB 541.9MB 911 900
Sysdb 102.3MB 597.5MB 597.5MB 0 -500
```

### 21.7.4.9 show monitor hadoop

The **show monitor hadoop** command displays a list of jobs that are running on all monitored Hadoop clusters.

#### Command Mode

EXEC

#### Command Syntax

```
show monitor hadoop
```

#### Example

This command displays the jobs that are running on all monitored clusters.

```
switch> show monitor hadoop
Last updated: 2013-10-06 18:14:23
Currently running jobs: 4
JobId Job Name Cluster Maps (#/%) Reduces (#/%) Start Time
---- ----- -----

switch>
```

---

#### 21.7.4.10 show monitor hadoop cluster all

The **show monitor hadoop cluster all** command displays configuration and connection information for all monitored Hadoop clusters.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster all
```

##### Example

This command displays configuration and connection data for all connected Hadoop clusters.

```
switch> show monitor hadoop cluster all

Total number of clusters configured: 3
Cluster : Cluster0
Admin status : Enabled
JobTracker host : host0
JobTracker RPC port : 9000
JobTracker user : user0
JobTracker polling interval : 100 seconds
TaskTracker HTTP port : 8800
Operational status : Enabled
Active TaskTrackers : 31
Blacklisted TaskTrackers : 1
Decommissioned TaskTrackers : 1
Tracker expiry interval : 20.0
Map slots (used/total) : 10/100
Reduce slots (used/total) : 11/110
JobTracker heap size : 1.04GB (max: 2.08GB)

Cluster : Cluster1
Admin status : Enabled
JobTracker host : host1
JobTracker RPC port : 9001
JobTracker user : user1
JobTracker polling interval : 101 seconds
TaskTracker HTTP port : 8801
Operational status : Enabled
Active TaskTrackers : 32
Blacklisted TaskTrackers : 0

Tracker expiry interval : 40.0
Map slots (used/total) : 20/200
Reduce slots (used/total) : 22/220
JobTracker heap size : 2.09GB (max: 4.15GB)

Cluster : Cluster2
Admin status : Disabled
JobTracker host : host2
JobTracker RPC port : 9002
JobTracker user : user2
JobTracker polling interval : 102 seconds
TaskTracker HTTP port : 8802
Operational status : Disabled
```

#### 21.7.4.11 show monitor hadoop cluster counters

The `show monitor hadoop cluster counters` command displays a list of jobs running on the specified Hadoop cluster and data consumption associated with these jobs.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name counters
```

##### Parameter

***c\_name*** Cluster name.

##### Example

This command displays jobs running on cluster ***Cluster0***.

```
switch> show monitor hadoop cluster Cluster0 counters
Last updated: 2013-10-06 18:14:23
Counters for currently running jobs on cluster: Cluster0
JobId Job Name User Bytes In Bytes Out Start Time
----- -----
2 ShortName2 JobUser2 37.36GB 76.29MB 2013-10-06 17:37:43
1 ReallyAVeryLon\ JobUser1 37.36GB 76.29MB 2013-10-06 17:56:03
gNameForAJob1 switch>
```

---

#### 21.7.4.12 show monitor hadoop cluster history

The `show monitor hadoop cluster history` command displays all jobs that ran on the specified cluster. The list includes all jobs that ran since the switch was reloaded, the job history was cleared ([clear monitor hadoop job-history](#)), or MapReduce Tracer was enabled.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name history
```

##### Parameter

***c\_name*** Cluster name.

##### Example

This command displays the jobs that were ran on the cluster named ***Cluster0***.

```
switch> show monitor hadoop cluster Cluster0 history

Jobs history on cluster: Cluster0
JobId Job Name Start Time End Time Bytes In Bytes Out
----- -----
2 AReallyBigHist\ 2013-10-06 2013-10-09 26.08GB 13.04GB

 oricalJobName 17:41:03 06:47:43
1 HistoryJob1 2013-10-06 2013-10-08 26.08GB 13.04GB
 17:57:43 00:31:03 switch>
```

#### 21.7.4.13 show monitor hadoop cluster history jobs

The **show monitor hadoop cluster history jobs** command displays data about the specified job. Hadoop jobs are identified by job number and the cluster that ran the job.

Data that the command returns include job identifiers, JobTracker ID, start and stop times, and data consumption.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name history jobs job_number
```

##### Parameters

- ***c\_name*** Cluster name.
- ***job\_number*** Job number. Value ranges from **0** to **2147483647**.

##### Example

This command displays information about **job 1** that ran on cluster **Cluster0**.

```
switch> show monitor hadoop cluster Cluster0 history job 1

Job history data for job: HistoryJob1
 Cluster : Cluster0
 Job Id : 1
 JT Id : 201310110013
 User : HistoryUser1
 Job start time : 2013-10-06 17:57:43
 Job end time : 2013-10-08 00:31:03

 Per Interface job counters:
 Interface TaskTracker Bytes In Bytes Out
 ----- -----
 Ethernet7 TaskTracker2 26.08GB 13.04GB
switch>
```

---

#### 21.7.4.14 show monitor hadoop cluster jobs

The `show monitor hadoop cluster jobs` command displays a list of jobs that are running on the specified cluster.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name jobs
```

##### Parameter

***c\_name*** Cluster name.

##### Example

This command displays the list of jobs running on cluster ***Cluster0***.

```
switch> show monitor hadoop cluster Cluster0 jobs
Last updated: 2013-10-06 18:14:23
Currently running jobs on cluster: Cluster0
JobId Job Name User Maps Reduces Start Time
----- -----
2 ShortName2 JobUser2 2 0 2013-10-06 17:37:43
1 ReallyAVeryLon\
gNameForAJob1 JobUser1 2 0 2013-10-06 17:56:03
switch>
```

#### 21.7.4.15 show monitor hadoop cluster jobs counter

The `show monitor hadoop cluster jobs counter` command displays data consumption and progress statistics for the specified job.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name [jobs job_number] counter
```

##### Parameters

- ***c\_name*** Cluster name.
- ***job\_number*** Job number. Value ranges from **0** to **2147483647**.

##### Example

This command displays byte counters for the job named **1** that is running on the cluster named **Cluster0**.

```
switch> show monitor hadoop cluster Cluster0 jobs 1 counters

Last updated: 2013-10-06 18:14:23
Cluster : Cluster0
Job Name : ReallyAVeryLongNameForAJob1
Job Id : 1
Interface HDFS Bytes Read HDFS Bytes Written Reduce Shuffle Bytes

Ethernet7 1.03GB 2.12MB 3.18MB
switch>
```

---

#### 21.7.4.16 show monitor hadoop cluster jobs <job number>

The **show monitor hadoop cluster jobs** **job number** command displays information about the specified job. Hadoop jobs are identified by job ID and the cluster that is running the job.

Data that the command returns include time of update, job identifiers, start times, data consumption, and completion progress.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name [jobs job_number]
```

##### Parameters

- ***c\_name*** Cluster name.
- ***job\_number*** Job number. Value ranges from **0** to **2147483647**.

##### Example

This command displays information about **job 1** that is running on cluster **Cluster0**.

```
switch> show monitor hadoop cluster Cluster0 jobs 1

Last updated: 2013-10-06 18:14:23
Information for job: ReallyAVeryLongNameForAJob1 running on cluster: Cluster0

 Name : ReallyAVeryLongNameForAJob1
 User : JobUser1
 Priority : veryHigh
 Running state : running
 Number of map tasks : 2
 Number of reduce tasks : 0
 Start time : 2013-10-06 17:56:03
 Bytes In : 37.36GB
 Bytes Out : 76.29MB
 Map Progress : 12.34%
 Reduce Progress : 13.45%
 Cleanup Progress : 14.56%
 Setup Progress : 15.67%

switch>
```

#### 21.7.4.17 show monitor hadoop cluster status

The `show monitor hadoop cluster status` command displays configuration and connection information for the specified cluster.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name status
```

##### Parameter

***c\_name*** Cluster name.

##### Example

This command displays configuration and connection data for the ***Cluster0*** cluster.

```
switch> show monitor hadoop cluster Cluster0 status

Last updated: 2013-10-06 18:14:23
Cluster status for cluster: Cluster0
 Admin status : Enabled
 JobTracker host : host0
 JobTracker RPC port : 9000
 JobTracker user : user0
 JobTracker polling interval : 100 seconds
 TaskTracker HTTP port : 8800
 Operational status : Enabled
 Active TaskTrackers : 31
 Blacklisted TaskTrackers : 1
 Decommissioned TaskTrackers : 1
 Tracker expiry interval : 20.0
 Map slots (used/total) : 10/100
 Reduce slots (used/total) : 11/110
 JobTracker heap size : 1.04GB (max: 2.08GB)

switch>
```

---

#### 21.7.4.18 show monitor hadoop cluster tasktracker

The `show monitor hadoop cluster tasktracker` command displays a list of TaskTrackers in the specified cluster. The IP address and access interface is included in the table.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop cluster c_name tasktracker
```

##### Parameter

*c\_name* Cluster name.

##### Example

This command displays the TaskTrackers on the **Cluster0** cluster.

```
switch> show monitor hadoop cluster Cluster0 tasktracker

Last updated: 2013-10-06 18:14:23
Total 2 TaskTrackers on cluster Cluster0:
Node IP Address Interface Maps Reduces
----- ----- -----
TaskTracker1 10.100.0.1 Ethernet7 4 0
TaskTracker2 10.100.0.2 Port-Channel7 4 0 switch>
```

#### 21.7.4.19 show monitor hadoop counters

The `show monitor hadoop counters` command displays byte counter data for all jobs running on clusters for which MapReduce Tracer is configured.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop counters
```

##### Example

This command displays byte counter data for all jobs running on clusters that the switch is accessing through MapReduce Tracer.

```
switch> show monitor hadoop counters
Last updated: 2013-10-06 18:14:23
Counters for running jobs:

```

---

#### 21.7.4.20 show monitor hadoop history

The **show monitor hadoop history** command displays jobs that ran on clusters for which MapReduce Tracer is configured. The list includes all jobs that ran since the switch was reloaded, MapReduce Tracer was enabled, or the job history was cleared ([clear monitor hadoop job-history](#)).

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop history
```

##### Example

This command displays data that jobs that previously ran on connected Hadoop clusters.

```
switch> show monitor hadoop history

Job history for all clusters:
JobId Job Name Cluster Start Time End Time Bytes In Bytes Out

 17:57:43 00:31:03
switch>
```

#### 21.7.4.21 show monitor hadoop status

The `show monitor hadoop status` command displays system status for MapReduce Tracer.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop status
```

##### Example

This command displays MapReduce Tracer status for all connected clusters and TaskTrackers.

```
switch> show monitor hadoop status
Last updated: 2013-10-06 18:14:23
Mapreduce Tracer status:
 Admin status : Enabled
 Operational status : Enabled
 Number of clusters configured : 3
 Number of local TaskTrackers : 4
 Number of jobs running locally : 4 switch>
```

---

#### **21.7.4.22 show monitor hadoop tasktracker all**

The **show monitor hadoop tasktracker all** command displays a list of TaskTrackers that are on all monitored Hadoop clusters.

##### **Command Mode**

EXEC

##### **Command Syntax**

```
show monitor hadoop tasktracker all
```

##### **Example**

This command displays the TaskTrackers of all monitored clusters that are connected to the switch.

```
switch> show monitor hadoop tasktracker all
Last updated: 2013-10-06 18:14:23
All local TaskTrackers:
Node Cluster IP Address Interface Maps Reduces
----- -----
TaskTracker1 Cluster0 10.100.0.1 Ethernet7 4 0
TaskTracker3 Cluster1 10.100.0.3 Ethernet8 4 0
TaskTracker2 Cluster0 10.100.0.2 Port-Channel7 4 0
TaskTracker4 Cluster1 10.100.0.4 Port-Channel8 4 0
switch>
```

#### 21.7.4.23 show monitor hadoop tasktracker all counters

The `show monitor hadoop tasktracker all counters` command displays byte counters for the TaskTrackers of all monitored Hadoop clusters.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop tasktracker all counters
```

##### Example

This command displays byte counter data for the TaskTrackers servicing all MapReduce Tracer Hadoop clusters.

```
switch> show monitor hadoop tasktracker all counters
Last updated: 2013-10-06 18:14:23
Counters for all TaskTrackers:
Node IP Address Interface Bytes Read Bytes Written

TaskTracker1 10.100.0.1 Ethernet7 2.08GB 4.24MB
TaskTracker3 10.100.0.3 Ethernet8 6.23GB 12.72MB

TaskTracker4 10.100.0.4 Port-Channel8 8.30GB 16.95MB
switch>
```

#### 21.7.4.24 show monitor hadoop tasktracker counters

The **show monitor hadoop tasktracker counters** command displays a list of jobs running on the specified TaskTracker and output from byte counters associated with these jobs.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop tasktracker NODES counters
```

##### Parameters

- **NODES** TaskTracker node access point. Options include:
  - **host *hostname*** Node name.
  - **interface ethernet *e\_range*** Ethernet interfaces through which node connects.
  - **interface port-channel *p\_range*** Port channel interfaces through which node connects.

##### Examples

- This command displays the jobs running on the TaskTracker on the **TaskTracker1** node.

```
switch> show monitor hadoop tasktracker host TaskTracker1 counters

#### 21.7.4.25 show monitor hadoop tasktracker jobs

The `show monitor hadoop tasktracker jobs` command displays data about the jobs that are running on TaskTrackers located on the specified node or accessed through the listed interfaces.

Including a cluster parameter filters results to include data only from the cluster polled by the specified monitor.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop tasktracker NODES jobs [CLUSTERS]
```

##### Parameters

- **NODES** TaskTracker node access point. Options include:
  - **host *hostname*** Node name.
  - **interface ethernet *e\_range*** Ethernet interfaces through which node connects.
  - **interface port-channel *p\_range*** Port channel interfaces through which node connects.
- **CLUSTERS** Hadoop cluster for which command displays data. Options include:
  - **no parameter** TaskTracker on specified **NODE** can be in any cluster.
  - **cluster *c\_name*** TaskCluster on specified **NODE** must be in named cluster.

##### Examples

- This command displays data for jobs running on **TaskTracker1**.

```
switch> show monitor hadoop tasktracker host TaskTracker1 jobs

Last updated: 2013-10-06 18:14:23
Running job for TaskTracker: TaskTracker1
JobId Job Name Cluster Maps(#/%) Reduces(#/%) Start Time
----- -----

#### 21.7.4.26 show monitor hadoop tasktracker running-tasks

The `show monitor hadoop tasktracker running-tasks` command displays progress and byte counts of tasks executed by TaskTrackers located on the specified node or accessed through the listed interfaces.

Including a cluster-ID parameter filters results to include data only from the specified cluster.

##### Command Mode

EXEC

##### Command Syntax

```
show monitor hadoop tasktracker NODES running-tasks [CLUSTERS][JOBS]
```

##### Parameters

- **NODES** TaskTracker node access point. Options include:
  - **host *hostname*** Node name.
  - **interface ethernet *e\_range*** Ethernet interfaces through which node connects.
  - **interface port-channel *p\_range*** Port channel interfaces through which node connects.
- **CLUSTERS** Hadoop cluster for which command displays data. Options include:
  - **no parameter** TaskTracker on specified **NODE** can be in any cluster.
  - **cluster *c\_name*** TaskCluster on specified **NODE** must be in named cluster.
- **JOB**S Job list. Options include:
  - **no parameter** all jobs.
  - **job *0* to *2147483647*** Specifies number of single job.

##### Examples

- This command displays data for tasks running on TaskTracker named **TaskTracker1**.

```
switch> show monitor hadoop tasktracker host TaskTracker1 running-tasks

Last updated: 2013-10-06 18:14:23

### 21.7.4.27 show monitor hadoop tasktracker running-tasks cluster job task

The `show monitor hadoop tasktracker running-tasks cluster job task` command displays detailed data for the specified task.

#### Command Mode

EXEC

#### Command Syntax

```
show monitor hadoop tasktracker NODE [running-tasks cluster name][job jnum][task tum]
```

#### Parameters

- **NODE** TaskTracker node access point. Options include:
  - **host *hostname*** Node name.
  - **interface ethernet *e\_range*** Ethernet interfaces through which node connects.
  - **interface port-channel *p\_range*** Port channel interfaces through which node connects.
- ***name*** Cluster name.
- ***jnum*** Job number. Value ranges from **0** to **2147483647**.
- ***tum*** Task number. Value ranges from **0** to **2147483647**.

#### Examples

- This command displays data for **task 1 of job 1** on **TaskTracker1** of **Cluster0**.

```
switch> show monitor hadoop tasktracker host TaskTracker1 running-tasks cluster Cluster0 job 1
task 1

Last updated: 2013-10-06 18:14:23
Task details for one task as given below:
 TaskTracker name : TaskTracker1
 Interface : 'Ethernet7'
 Cluster : Cluster0
 Job Id : 1
 Task Id : 1
 Attempt Id : 0
 Task type : Map
 Status : running
 State : running
 Start time : 2013-10-06 17:57:43
 Progress : 50.00%
 HDFS bytes read : 1.05MB
 HDFS bytes written : 1.07MB
 Reduce shuffle bytes : 1.48MB
switch>
```

- This command displays data for **task 1 of job 1** on the **Cluster0** TaskTracker that is accessible through **Ethernet interface 7**.

#### 21.7.4.28 show monitor hadoop tasktracker status

The `show monitor hadoop tasktracker status` command displays connection and activity information for the TaskTracker on the specified clusters or accessed through the specified interface. The following command formats display the listed TaskTracker information:

- `show monitor hadoop cluster c_name tasktracker status`: TaskTrackers on specified cluster.
- `show monitor hadoop tasktracker NODES status`: TaskTrackers on specified nodes or interfaces.
- `show monitor hadoop tasktracker all status`: all connected TaskTrackers.

#### Command Mode

EXEC

#### Command Syntax

```
show monitor hadoop cluster c_name tasktracker status
show monitor hadoop tasktracker NODES status
show monitor hadoop tasktracker all status
```

#### Parameters

- `c_name` Cluster name.
- `NODES` TaskTracker node access point. Options include:
  - `host hostname` Node name.
  - `interface ethernet e_range` Ethernet interfaces through which node connects.
  - `interface port-channel p_range` Port channel interfaces through which node connects.

#### Examples

- This command displays connection and activity information for all TaskTrackers connected through Ethernet interfaces **7** and **8**.

```
switch> show monitor hadoop tasktracker interface Ethernet7,8 status
Last updated: 2013-10-06 18:14:23
TaskTracker : TaskTracker1
IP Address : 10.100.0.1

---

#### 21.7.4.29 show monitor hadoop traffic burst

The **show monitor hadoop traffic burst** command displays the largest data bursts for specified Hadoop cluster jobs. A data burst is the data consumed during a polling interval. The command displays input and output burst:

- Input bursts include bytes written to the host.
- Output bursts include bytes written by the host.

#### Command Mode

EXEC

#### Command Syntax

```
show monitor hadoop [CLUSTERS] traffic burst [NODE]
```

#### Parameters

- **CLUSTERS** Hadoop clusters for which command displays data. Options include:
  - **no parameter** All clusters.
  - **cluster c\_name** Cluster name.
- **NODES** TaskTracker node access point. Options include:
  - **host hostname** Node name.
  - **interface ethernet e\_range** Ethernet interfaces through which node connects.
  - **interface port-channel p\_range** Port channel interfaces through which node connects.

#### Examples

- This command displays traffic burst data for all running jobs.

```
switch> show monitor hadoop traffic burst

### 21.7.4.30 show monitor system

The **show monitor system** command displays information about the memory usage status of the system including when low-memory situations have led to Out-Of-Memory (OOM) events.

#### Command Mode

EXEC

#### Command Syntax

```
show monitor system
```

#### Examples

- The following output is for a system where the feature is disabled and the system has never entered the low-memory mode.

```

Memory Exhaustion Feature enabled: False
System currently in Memory Exhaustion: False
Number of times system entered Memory Exhaustion: 0

```

- The following output is for a system where the feature is enabled and the system has never entered the low-memory mode.

```

Memory Exhaustion Feature enabled: True
System currently in Memory Exhaustion: False
Number of times system entered Memory Exhaustion: 0

```

- The following output is for a system where the feature is enabled and the system enters the low-memory mode.

```

Memory Exhaustion Feature enabled: True
System currently in Memory Exhaustion: True
Number of times entered Memory Exhaustion: 1
Last time entered in Memory Exhaustion: 0:00:07 ago

```

- The following output is for a system where the feature is enabled and the system enters the low-memory mode once, and has exited the low-memory mode.

```

Memory Exhaustion Feature enabled: True
System currently in Memory Exhaustion: False
Last time entered in Memory Exhaustion: 0:01:00 ago
Last time exited from Memory Exhaustion: 0:00:05 ago

```

#### 21.7.4.31 shutdown (Monitor-Hadoop)

The **shutdown** command globally disables MapReduce Tracer on the switch. Enabling MapReduce Tracer for an individual cluster requires the feature to be globally enabled through this command and enabled for the individual cluster thorough the [shutdown \(Monitor Hadoop Cluster\)](#) command. By default, MapReduce Tracer is globally disabled.

The **no shutdown** command globally enables MapReduce Tracer. The **shutdown** and **default shutdown** commands globally disable MapReduce Tracer by removing the corresponding **no shutdown** command from *running-config*.

##### Command Mode

Monitor-Hadoop Configuration

##### Command Syntax

```
shutdown
no shutdown
default shutdown
```

##### Related Command

The [monitor hadoop](#) command places the switch in the Monitor-Hadoop Configuration Mode.

##### Examples

- These commands globally enable MapReduce Tracer.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# no shutdown
switch(config-monitor-hadoop)# show active
 monitor hadoop
 no shutdown
switch(config-monitor-hadoop) #
```

- This command globally disables MapReduce Tracer.

```
switch(config-monitor-hadoop)# shutdown
switch(config-monitor-hadoop)# show active
switch(config-monitor-hadoop) #
```

---

#### 21.7.4.32 shutdown (Monitor Hadoop Cluster)

The **shutdown** command disables MapReduce Tracer for the configuration mode cluster. Globally disabling MapReduce Tracer ([show monitor hadoop](#)) also disables the function on the individual cluster. Enabling MapReduce Tracer for the cluster requires the function to be enabled globally and for the individual cluster.

The **no shutdown** command configures the MapReduce Tracer setting as **enabled** for the configuration mode cluster. The **shutdown** and **default shutdown** commands disable MapReduce Tracer for the cluster by removing the corresponding **no shutdown** command from **running-config**.

#### Command Mode

Monitor-Hadoop-Cluster Configuration

#### Command Syntax

```
shutdown
no shutdown
default shutdown
```

#### Related Command

The [cluster \(Monitor Hadoop\)](#) command places the switch in the **monitor-hadoop-cluster** configuration mode.

#### Examples

- These commands globally enable MapReduce Tracer, then enables it for the **CL2** cluster.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# no shutdown
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# no shutdown
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
 no shutdown
switch(config-monitor-hadoop-CL2)# exit
switch(config-monitor-hadoop)# show active
monitor hadoop
 no shutdown
 cluster CL2
 no shutdown
switch(config-monitor-hadoop) #
```

- These commands disable MapReduce Tracer for the **CL2** cluster. MapReduce Tracer remains globally enabled.

```
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# shutdown
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
switch(config-monitor-hadoop-CL2)# exit
switch(config-monitor-hadoop)# show active
monitor hadoop
 no shutdown
 cluster CL2
switch(config-monitor-hadoop) #
```

### 21.7.4.33 tasktracker (Monitor Hadoop Cluster)

The **tasktracker** command specifies the HTTP port for accessing TaskTrackers of the Hadoop cluster monitored through configuration mode statements. The switch compiles a list of the cluster's TaskTracker addresses by periodically polling the cluster's JobTracker ([jobtracker \(Monitor Hadoop Cluster\)](#)). The default TaskTracker HTTP port is **50060**.

The **no tasktracker** and **default tasktracker** commands restore the configuration mode TaskTracker HTTP port to **50060** by removing the corresponding **tasktracker** command from **running-config**.

#### Command Mode

Monitor-Hadoop Configuration

#### Command Syntax

```
tasktracker http-port port_number
no tasktracker http-port
default tasktracker http-port
```

#### Parameter

**port\_num** TaskTracker HTTP port number. Value ranges from **1** to **65535**. Default value is **50060**.

#### Related Command

The [cluster \(Monitor Hadoop\)](#) command places the switch in the Monitor-Hadoop Configuration Mode.

#### Examples

- These commands specify a TaskTracker HTTP port address of **51000**.

```
switch(config)# monitor hadoop
switch(config-monitor-hadoop)# cluster CL2
switch(config-monitor-hadoop-CL2)# tasktracker http-port 51000
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
 tasktracker http-port 51000
switch(config-monitor-hadoop-CL2) #
```

- These commands restore the default TaskTracker HTTP port address of **50060**.

```
switch(config-monitor-hadoop-CL2)# no tasktracker http-port
switch(config-monitor-hadoop-CL2)# show active
monitor hadoop
 cluster CL2
switch(config-monitor-hadoop-CL2)# show active all
monitor hadoop
 cluster CL2
 jobtracker rpc-port 8021
 tasktracker http-port 50060
 interval 10
 shutdown
switch(config-monitor-hadoop-CL2) #
```

## 21.8 Transceiver Performance Monitoring

- [Transceiver Performance Monitoring Overview](#)

- 
- Configuring Transceiver Performance Monitoring
  - Transceiver Performance Monitoring Limitations
  - Transceiver Performance Monitoring Show Commands
  - Transceiver Performance Monitoring Commands

## 21.8.1 Transceiver Performance Monitoring Overview

The Transceiver Performance Monitoring and Enhanced Diagnostics enables viewing the Digital Optical Monitoring (DOM) parameters for the optics that support enhanced diagnostics. Use the `show` commands to view the instantaneous values for various PAM4 parameters such as Signal-To-Noise Ratio, Residual Inter Symbol Interference, PAM4 Level Transition Parameters, and other parameters supported on optics interfaces.

Using the Performance Monitoring feature allows EOS to collect and maintain certain performance statistics over a user-defined time. EOS stores data for two intervals: the current interval and the most recently completed interval. When the current interval ends, EOS saves the data as the previous interval so a new current interval can start, and the old previous interval data discarded.

## 21.8.2 Configuring Transceiver Performance Monitoring

EOS enables the Digital Optical Monitoring (DOM) on all interfaces and you cannot disable the feature.

EOS disables Performance Monitoring on all interfaces by default. Use the `performance-monitoring transceiver default` configuration command to enable Performance Monitoring on all interfaces across the system.

```
switch(config)# performance-monitoring transceiver default
```

Enable Performance Monitoring on a per interface basis using the `performance-monitoring transceiver` configuration command.

```
switch(config)# interface Ethernet8/1
switch(config-if-Et8/1)# performance-monitoring transceiver
```

Configure the Performance Monitoring period using the `performance-monitoring period <period>` configuration command.

```
switch(config)# performance-monitoring period 60s
```

The command configures the performance monitoring period to **60** seconds across the system. This command supports configuring the performance monitoring period in units of either seconds, minutes, hours or days. For example, use `performance-monitoring period 30` minutes to configure the period as **30** minutes, `performance-monitoring period 2` hours to configure the period as **2** hours and so on. The default performance-monitoring period is **15** minutes.

Use the **no** form of these commands to revert the configuration.

100GBASE-FR, 100GBASE-LR and 100GBASE-DR do not have thresholds for enhanced Digital Optical Monitoring (DOM) parameters, so these parameters and their thresholds do not display in the output of `show interfaces transceiver dom thresholds` command.

```
switch# show interfaces Ethernet8/1 transceiver dom thresholds
Ch: Channel, mA: milliamperes, dBm: decibels (milliwatts),
C: Celsius, V: Volts, NA or N/A: not applicable.

Ethernet8/1
```

| Parameter        | Ch | Value  | High Threshold | Alarm Threshold | High Warn Threshold | Low Warn Threshold | Low Alarm Threshold | Unit | Indicator |
|------------------|----|--------|----------------|-----------------|---------------------|--------------------|---------------------|------|-----------|
| <hr/>            |    |        |                |                 |                     |                    |                     |      |           |
| Temperature      | -  | 58.87  | 72.00          | 65.00           | 5.00                | -2.00              | -2.00               | C    |           |
| Voltage          | -  | 3.28   | 3.56           | 3.47            | 3.14                | 3.04               | 3.04                | V    |           |
| TX bias current  | 1  | 83.90  | 131.00         | 120.00          | 35.00               | 30.00              | 30.00               | mA   |           |
|                  | 2  | 85.30  | 131.00         | 120.00          | 35.00               | 30.00              | 30.00               | mA   |           |
| Optical TX power | 1  | -10.51 | -6.99          | -8.00           | -11.00              | -12.00             | -12.00              | dBm  |           |
|                  | 2  | -9.70  | -6.99          | -8.00           | -11.00              | -12.00             | -12.00              | dBm  |           |
| Optical RX power | 1  | -0.99  | 6.99           | 6.02            | -2.00               | -3.01              | -3.01               | dBm  |           |

## Examples

Use the following command to display DOM parameters for a 400GBASE-ZR interface:

```
switch# show show interfaces Ethernet27/1 transceiver dom
Ch: Channel, N/A: not applicable, TX: transmit, RX: receive
mA: milliamperes, dBm: decibels (milliwatts), C: Celsius, V: Volts

Port 27
Last update: 0:00:03 ago
 Value

Case temperature 65.00 C
Voltage 3.29 V
TX power -8.29 dBm
RX total power -9.13 dBm
RX channel power -9.53 dBm
Pre-FEC BER 6.07e-04
Post-FEC errored frames ratio 0.00e+00
Chromatic dispersion (short link) 2.00 ps/nm
Differential group delay 4.00 ps
SOPMD 34.00 ps^2
Polarization dependent loss 0.60 dB
Received OSNR estimate 36.40 dB
Received ESNR estimate 18.00 dB
Carrier frequency offset 923.00 MHz
SOP rate of change 0.00 krad/s
Laser temperature 52.82 C
Laser frequency 193100.00 GHz
```

Use the following command to display DOM parameters for a 100GBASE-DR interface:

```
switch# show interfaces Ethernet30/1 transceiver dom
Ch: Channel, N/A: not applicable, TX: transmit, RX: receive
mA: milliamperes, dBm: decibels (milliwatts), C: Celsius, V: Volts

Port 30
Last update: 0:00:00 ago
 Value

Temperature 55.16 C
Voltage 3.37 V
Aggregate TX Power -40.00 dBm
Aggregate RX Power -33.98 dBm
TEC current -32.30 mA
Temperature error 0.01 C
Ethernet30/1 (Channel 1)
TX bias current 0.00 mA
Optical TX power -30.00 dBm
Optical RX power -30.00 dBm
Pre-FEC BER 3.67e-04
Uncorrected BER 0.00e+00
SNR 0.00 dB
```

### 21.8.3 Transceiver Performance Monitoring

100GBASE-FR, 100GBASE-LR and 100GBASE-DR do not have thresholds of enhanced Digital Optical Monitoring (DOM) parameters, so these parameters and thresholds do not display in the output of CLI command **show interfaces transceiver dom thresholds**.

```
switch# show interfaces Ethernet8/1 transceiver dom thresholds
Ch: Channel, mA: milliamperes, dBm: decibels (milliwatts),
C: Celsius, V: Volts, NA or N/A: not applicable.

Ethernet8/1
Last update: 0:00:02 ago
 High Alarm High Warn Low Warn Low Alarm
Parameter Ch Value Threshold Threshold Threshold Threshold Unit Indicator

Temperature - 58.87 72.00 65.00 5.00 -2.00 C
Voltage - 3.28 3.56 3.47 3.14 3.04 V
TX bias current 1 83.90 131.00 120.00 35.00 30.00 mA
 2 85.30 131.00 120.00 35.00 30.00 mA
Optical TX power 1 -10.51 -6.99 -8.00 -11.00 -12.00 dBm
 2 -9.70 -6.99 -8.00 -11.00 -12.00 dBm
Optical RX power 1 -0.99 6.99 6.02 -2.00 -3.01 dBm
```

### 21.8.4 Displaying Transceiver Performance Monitoring

Use the **show interfaces transceiver dom** command to display the Digital Optical Monitoring (DOM) parameters. The output displays parameters most recently read.

```
switch# show interfaces Ethernet8/1 transceiver dom
Ch: Channel, N/A: not applicable, TX: transmit, RX: receive
mA: milliamperes, dBm: decibels (milliwatts), C: Celsius, V: Volts

Ethernet8/1
Last update: 0:00:03 ago
 Parameter Ch Value Unit

Temperature - 58.97 C
Voltage - 3.28 V
TX bias current 1 83.61 mA
 2 85.15 mA
Optical TX power 1 -10.60 dBm
 2 -9.79 dBm
Optical RX power 1 -0.84 dBm
 2 -2.28 dBm
SNR 1 17.46 dB
 2 15.89 dB
Residual ISI 1 0.00 ps/nm
 2 0.00 ps/nm
Level transitions 1 829.00
 2 3055.00
TEC current error 1 -527.60 mA
 2 -365.70 mA
Frequency error 1 -0.48 GHz
 2 0.00 GHz
Pre-FEC BER - 1.53e-03
Uncorrected BER - 0.00e+00
```

Use the **show interfaces transceiver dom thresholds** command to display the Digital Optical Monitoring (DOM) parameters and thresholds. The output displays parameters most recently read.

```
switch# show interfaces Ethernet8/1 transceiver dom thresholds
Ch: Channel, mA: milliamperes, dBm: decibels (milliwatts),
C: Celsius, V: Volts, NA or N/A: not applicable.

Ethernet8/1

|                   | 2 | -0.06    | 5.12     | 2.56     | -2.56   | -5.12   | GHz   |       |
| Pre-FEC BER       | - | 1.47e-03 | 1.00e-04 | 1.00e-05 | N/A     | N/A     |       | ALARM |
| Uncorrected BER   | - | 0.00e+00 | 0.00e+00 | 0.00e+00 | N/A     | N/A     |       |       |

The Indicator column in the output above gives an indication of where the value lies with respect to the threshold. No output displays when the parameter falls in the expected range between the Low Warn and High Warn thresholds. If the value becomes greater than or equal to the High Alarm or less than or equal to the Low Alarm, **ALARM** displays in the output. If the value becomes greater than or equal to the High Warn (but less than the High Alarm) or less than or equal to the Low Warn (but greater than the Low Alarm), **WARN** displays in the output.

Use the **show interfaces transceiver performance-monitoring** command to display the performance monitoring statistics from the CLI. This command displays data only if you enable the feature using the configuration command **transceiver performance-monitoring**.

```
switch# show interfaces Ethernet8/1 transceiver performance-monitoring
Ch: Channel, N/A: not applicable

Performance monitoring period : 0:15:00
Ethernet8/1
Parameter Ch Value

Current Interval 0
 Started - 0:00:12 ago

```

- **Performance Monitoring Period: 0:15:00** - Indicates the length of one Performance Monitoring period. **0:15:00** specifies a period of **15** minutes, the default value for this parameter. The Performance Monitoring period can be configured using the **performance-monitoring period** configuration command.
- **Started: 0:00:12 ago** - Indicates the time the host started the performance monitoring interval.

- **Last Update: 0:00:02 ago** - Indicates the last time the host read the diagnostic parameters from the module. The host samples values every six seconds.
- **Pre-FEC BER avg, Uncorrected BER avg** - The average The average Bit Error Rate (BER) before Forward Error Correction (FEC) value so far in the indicated performance monitoring interval.
- **Pre-FEC BER min, Uncorrected BER min** - The minimum BER value so far in the indicated performance monitoring interval.
- **Pre-FEC BER max, Uncorrected BER max** - The maximum BER value so far in the indicated performance monitoring interval.
- **Pre-FEC BER high warn exceeded, Uncorrected BER high warn exceeded, Pre-FEC BER high alarm exceeded, Uncorrected BER high alarm exceeded** - The number of times the host read a value which was greater than the indicated threshold. The host reads values and checks exceeded thresholds every six seconds. This provides only an indication of the actual exceeded count.
- **Temperature warn exceeded, Temperature alarm exceeded** - The number of times the host read a value which was outside the range of the indicated threshold. The host reads values and checks exceeded thresholds every six seconds. This provides only an indication of the actual exceeded count.

The **show interfaces transceiver performance-monitoring thresholds** command displays the performance monitoring statistics and their thresholds from the CLI. This command only displays data only if the feature has been enabled using the configuration command performance-monitoring transceiver.

The following output only displays data for the datapath primary lanes nested under the configured Ethernet interface for the transceiver. The output lists the lanes under the header, **index**, since the lanes can represent either a datapath, electrical lane, or optical channel for each parameter.

- Performance Monitoring Period: 0:15:00** - Indicates the length of one performance monitoring period. 0:15:00 specifies a period of 15 minutes, the default time period. Use the [performance-monitoring period](#) command to configure the performance monitoring period.
- Started: 0:00:12 ago** - Indicates the time that the host started the performance monitoring interval.
- Last Update: 0:00:02 ago** - Indicates the last reading of the diagnostic parameter by the host. The host samples data every six (6) seconds.
- Pre-FEC BER avg, Uncorrected BER avg** - The average Bit Error Rate (BER) before Forward Error Correction (FEC) value in the indicated performance monitoring interval calculated by the host.
- Pre-FEC BER min, Uncorrected BER min** - The minimum BER value in the indicated performance monitoring interval calculated by the host.
- Pre-FEC BER max, Uncorrected BER max** - The maximum BER value in the indicated performance monitoring interval calculated by the host.

The [show interfaces interface transceiver performance-monitoring thresholds](#) command can be used to display the performance monitoring statistics and thresholds from the CLI. This command displays data only if you enable performance monitoring on the switch.

In the output, several alarms occurred on the interface:

- **Pre-FEC BER high warn exceeded**
- **Uncorrected BER high warn exceeded**
- **Pre-FEC BER high alarm exceeded**
- **Uncorrected BER high alarm exceeded**

Indicates the number of times the host read a value greater than the configured threshold. The host reads values and checks exceeded thresholds every six seconds. This only provides an indication of the actual exceeded count.

- **Temperature warn exceeded**
- **Temperature alarm exceeded**

Indicates the number of times the host read a value outside the configured range. The host reads values and checks exceeded thresholds every six seconds. This only provides an indication of the actual exceeded count.

## 21.8.5 Transceiver Performance Monitoring Commands

### Global Configuration Commands

- [performance-monitoring period](#)
- [performance-monitoring transceiver default](#)

### Interface Configuration Command

- [performance-monitoring transceiver](#)

### Show Commands

- [show interfaces transceiver dom](#)

- [show interfaces transceiver dom thresholds](#)
- [show interfaces transceiver performance-monitoring](#)
- [show interfaces transceiver performance-monitoring thresholds](#)

---

### 21.8.5.1 performance-monitoring period

The **performance-monitoring period** command configures Performance Monitoring Period across the system.

The **no performance-monitoring period** command removes the Performance Monitoring Period configuration from the *running-config*.

#### Command Mode

Global Configuration Mode

#### Command Syntax

```
performance-monitoring period period
no performance-monitoring period period
```

#### Parameter

***period*** - Specify the performance monitoring period in units of either seconds, minutes, hours or days. The default performance-monitoring period is **15** minutes.

#### Example

This command configures the performance monitoring period to **60** seconds across the system.

```
switch(config)# performance-monitoring period 60s
```

### 21.8.5.2 performance-monitoring transceiver

The **performance-monitoring transceiver** command enable Performance Monitoring on a per interface basis.

The **no performance-monitoring transceiver** command removes the Performance Monitoring configuration from the *running-config*.

#### Command Mode

Interface Configuration Mode

#### Command Syntax

```
performance-monitoring transceiver
no performance-monitoring transceiver
```

#### Example

This command enables the Performance Monitoring on a per interface basis.

```
switch(config)# interface Ethernet8/1
switch(config-if-Et8/1)# performance-monitoring transceiver
```

---

### 21.8.5.3 performance-monitoring transceiver default

The **performance-monitoring transceiver default** command enable Performance Monitoring on all interfaces across the system.

The **no performance-monitoring transceiver default** command removes the Performance Monitoring configuration from the *running-config*.

#### Command Mode

Global Configuration Mode

#### Command Syntax

```
performance-monitoring transceiver default
no performance-monitoring transceiver default
```

#### Example

This command enables the Performance Monitoring on all interfaces across the system.

```
switch(config)# performance-monitoring transceiver default
```

#### 21.8.5.4 show interfaces transceiver dom

The **show interfaces transceiver dom** command displays the Digital Optical Monitoring (DOM) parameters from the CLI. The output displays the most recently read parameters.

##### Command Mode

Privileged EXEC

##### Command Syntax

```
show interfaces interface transceiver dom
```

##### Parameter

**interface** - Specify the Ethernet interface name.

##### Example

This command displays the Digital Optical Monitoring (DOM) parameters.

```
switch# show interfaces Ethernet8/1 transceiver dom
Ch: Channel, N/A: not applicable, TX: transmit, RX: receive
mA: milliamperes, dBm: decibels (milliwatts), C: Celsius, V: Volts

Ethernet8/1
Last update: 0:00:03 ago
Parameter Ch Value Unit

Temperature - 58.97 C
Voltage - 3.28 V
TX bias current 1 83.61 mA
 2 85.15 mA
Optical TX power 1 -10.60 dBm
 2 -9.79 dBm
Optical RX power 1 -0.84 dBm
 2 -2.28 dBm
SNR 1 17.46 dB
 2 15.89 dB
Residual ISI 1 0.00 ps/nm
 2 0.00 ps/nm
Level transitions 1 829.00
 2 3055.00
TEC current error 1 -527.60 mA
 2 -365.70 mA
Frequency error 1 -0.48 GHz
 2 0.00 GHz
Pre-FEC BER - 1.53e-03
Uncorrected BER - 0.00e+00
```

## 21.8.5.5 show interfaces transceiver dom thresholds

The **show interfaces transceiver dom thresholds** command displays the Digital Optical Monitoring (DOM) parameters and thresholds.

### Command Mode

Privileged EXEC

### Command Syntax

**show interfaces *interface* transceiver dom thresholds**

### Parameter

**interface** - Specify the Ethernet interface name.

### Example

This command displays the Digital Optical Monitoring (DOM) parameters and thresholds.

| switch# show interfaces Ethernet8/1 transceiver dom thresholds |             |          |                      |                     |                    |                     |       |           |

### Command Output

The Indicator column in the output above gives an indication of where the value lies with respect to its thresholds. Nothing is shown when the parameter is in the expected range between the Low Warn and High Warn thresholds. If the value is greater than or equal to the High Alarm or less than or equal to the Low Alarm, **ALARM** is shown. If the value is greater than or equal to the High Warn (but less than the High Alarm) or less than or equal to the Low Warn (but greater than the Low Alarm), **WARN** is shown.

## 21.8.5.6 show interfaces transceiver performance-monitoring

The **show interfaces transceiver performance-monitoring** command displays the performance monitoring statistics from the CLI. This command displays data only if you enable Performance Monitoring on the switch.

### Command Mode

Privileged EXEC

### Command Syntax

```
show interfaces interface transceiver performance-monitoring
```

### Parameter

**INTERFACE** - Specify the Ethernet interface name.

### Example

This command displays the performance monitoring statistics from the CLI.

```
switch# show interfaces Ethernet8/1 transceiver performance-monitoring
Ch: Channel, N/A: not applicable

Performance monitoring period : 0:15:00
Ethernet8/1
Parameter Ch Value

Current Interval 0
 Started - 0:00:12 ago
 Last update - 0:00:02 ago
 Pre-FEC BER avg - 1.41e-03
 Pre-FEC BER high alarm exceeded - 0
 Pre-FEC BER high warn exceeded - 0
 Pre-FEC BER max - 1.54e-03
 Pre-FEC BER min - 5.93e-06
 Temperature alarm exceeded - 0
 Temperature warn exceeded - 0
 Uncorrected BER avg - 0.00e+00
 Uncorrected BER high alarm exceeded - 0
 Uncorrected BER high warn exceeded - 0
 Uncorrected BER max - 0.00e+00
 Uncorrected BER min - 0.00e+00
Interval 1
 Started - 0:15:13 ago
 Last update - 0:00:12 ago
 Pre-FEC BER avg - 1.53e-03
 Pre-FEC BER high alarm exceeded - 0
 Pre-FEC BER high warn exceeded - 0
 Pre-FEC BER max - 1.74e-03
 Pre-FEC BER min - 3.11e-05
 Temperature alarm exceeded - 0
 Temperature warn exceeded - 0
 Uncorrected BER avg - 0.00e+00
 Uncorrected BER high alarm exceeded - 0
 Uncorrected BER high warn exceeded - 0
 Uncorrected BER max - 0.00e+00
 Uncorrected BER min - 0.00e+00
```

### Command Output

#### Performance Monitoring Period: 0:15:00

This indicates the length of one Performance Monitoring period. **0:15:00** specifies a period of **15** minutes, which is the default value for this parameter. The Performance Monitoring period can be configured using the **performance-monitoring period configuration** command as described in the Configuration section.

---

**Started: 0:00:12 ago**

This indicates the time the host started the performance monitoring interval.

**Last Update: 0:00:02 ago**

This indicates the last time the host read the diagnostic parameters from the module. The host samples values every six seconds.

**Pre-FEC BER avg, Uncorrected BER avg**

This is the average value so far in the indicated performance monitoring interval.

**Pre-FEC BER min, Uncorrected BER min**

This is the minimum value so far in the indicated performance monitoring interval.

**Pre-FEC BER max, Uncorrected BER max**

This is the maximum value so far in the indicated performance monitoring interval.

**Pre-FEC BER high warn exceeded, Uncorrected BER high warn exceeded, Pre-FEC BER high alarm exceeded, Uncorrected BER high alarm exceeded**

This is the number of times the host read a value which was greater than the indicated threshold. The host reads values and checks exceeded thresholds every **6** seconds. Please note that this provides only an indication of the actual exceeded count.

**Temperature warn exceeded, Temperature alarm exceeded**

This is the number of times the host read a value which was outside the range of the indicated threshold. The host reads values and checks exceeded thresholds every six seconds. Note that this provides only an indication of the actual exceeded count.

### 21.8.5.7 show interfaces transceiver performance-monitoring thresholds

The **show interfaces transceiver performance-monitoring thresholds** command displays the performance monitoring statistics and thresholds from the CLI.

#### Command Mode

Privileged EXEC

#### Command Syntax

```
show interfaces interface transceiver performance-monitoring thresholds
```

#### Parameter

*interface* - Specify the Ethernet interface name.

#### Example

This command displays the performance monitoring statistics and thresholds.

| switch#show interfaces Ethernet8/1 transceiver performance-monitoring thresholds |                              |                     |          |          |                      |                     |                    |                     |

## 21.8.5.8 show interfaces transceiver dom thresholds

The **show interfaces transceiver dom thresholds** command displays the Digital Optical Monitoring (DOM) parameters and thresholds.

### Command Mode

Privileged EXEC

### Command Syntax

```
show interfaces interface transceiver dom thresholds
```

### Parameter

**interface** - Specify the Ethernet interface name.

### Example

This command displays the Digital Optical Monitoring (DOM) parameters and thresholds.

| switch#show interfaces Ethernet8/1 transceiver dom thresholds |             |          |                      |                     |                    |                     |       |           |

|                                                               | 2           | 15.89    | 40.00                | 39.00               | 19.00              | 18.00               | dB    | ALARM     |
| Residual ISI                                                  | 1           | 0.00     | 409.60               | 128.00              | -128.00            | -409.60             | ps/nm |           |
|                                                               | 2           | 0.00     | 409.60               | 128.00              | -128.00            | -409.60             | ps/nm |           |
| Level transitions                                             | 1           | 812.00   | 57344.00             | 53248.00            | 0.00               | 0.00                |       |           |
|                                                               | 2           | 3249.00  | 57344.00             | 53248.00            | 0.00               | 0.00                |       |           |
| TEC current error                                             | 1           | -504.70  | 409.60               | 128.00              | -128.00            | -409.60             | mA    | ALARM     |
|                                                               | 2           | -329.50  | 409.60               | 128.00              | -128.00            | -409.60             | mA    | WARN      |
| Frequency error                                               | 1           | -0.42    | 5.12                 | 2.56                | -2.56              | -5.12               | GHz   |           |
|                                                               | 2           | -0.06    | 5.12                 | 2.56                | -2.56              | -5.12               | GHz   |           |
| Pre-FEC BER                                                   | -           | 1.47e-03 | 1.00e-04             | 1.00e-05            | N/A                | N/A                 |       |           |
| Uncorrected BER                                               | -           | 0.00e+00 | 0.00e+00             | 0.00e+00            | N/A                | N/A                 |       | ALARM     |

### Command Output

The Indicator column in the output displays the value with respect to its thresholds. No data displays when the parameter occurs in the expected range between the Low Warn and High Warn thresholds. If the value is greater than or equal to the High Alarm or less than or equal to the Low Alarm, **ALARM** is shown. If the value is greater than or equal to the High Warn (but less than the High Alarm) or less than or equal to the Low Warn (but greater than the Low Alarm), **WARN** is shown.

### 21.8.5.9 show interfaces transceiver dom

The `show interfaces transceiver dom` command displays the Digital Optical Monitoring (DOM) parameters from the CLI. The displayed parameters are the most recently read, ‘instantaneous’ values.

#### Command Mode

Privileged EXEC

#### Command Syntax

```
show interfaces interface transceiver dom
```

#### Parameter

**interface** Specify the Ethernet interface name.

#### Example

This command displays the Digital Optical Monitoring (DOM) parameters.

```
switch#show interfaces Ethernet8/1 transceiver dom
Ch: Channel, N/A: not applicable, TX: transmit, RX: receive
mA: milliamperes, dBm: decibels (milliwatts), C: Celsius, V: Volts

Ethernet8/1
Last update: 0:00:03 ago
Parameter Ch Value Unit

Temperature - 58.97 C
Voltage - 3.28 V
TX bias current 1 83.61 mA
 2 85.15 mA
Optical TX power 1 -10.60 dBm
 2 -9.79 dBm
Optical RX power 1 -0.84 dBm
 2 -2.28 dBm
SNR 1 17.46 dB
 2 15.89 dB
Residual ISI 1 0.00 ps/nm
 2 0.00 ps/nm
Level transitions 1 829.00
 2 3055.00
TEC current error 1 -527.60 mA
 2 -365.70 mA
Frequency error 1 -0.48 GHz
 2 0.00 GHz
Pre-FEC BER - 1.53e-03
Uncorrected BER - 0.00e+00
```

## 21.9 NDR Sensor

The NDR switch sensor, also called the Monitor Security Awake feature, provides deep network analysis by doing deep packet inspection of some or all packets of traffic forwarded by the switch. NDR continuously monitors enterprise devices, users, and applications no matter the location, even as IP addresses change, while maintaining a forensic record of past activities. This functionality can be enabled or disabled on the fly without impacting regular packet forwarding functionality.

#### NDR Switch Sensor Extension

NDR switch sensor extends EOS telemetry for network threat detection. The FlowWatcher agent RPMs release as part of the `NDRSensor.swix` extension along with other RPMs that enable the NDR switch sensor functionality. Install the `NDRSensor.swix` extension on a system running a supported EOS version. After installing the extension, enable it using the `monitor security awake` command.

---

After enabling Monitor Security Awake, the FlowWatcher agent enables hardware flow tracking with filter-based packet sampling, IPv4 and IPv6 access lists, and mirroring features to receive the first few packets of every new flow and flow volume using IPFIX. It connects to the NDR Nucleus using SSL. The EOS FlowWatcher agent processes the most interesting packets of all the flows forwarded by the switch. The agent performs deep packet inspection (DPI) of the packets, computes flow volume using IPFIX data records, and generates activity records. The agent then sends the generated activity records to NDR Nucleus using Kafka over a TLS session. The NDR Nucleus then uses a combination of detection models to uncover malicious intent and provide the NDR functionality.

### Platform Compatibility

- CCS-720DF-48Y
  - CCS-720DP-24ZS
  - CCS-720DP-48ZS

  - [Configuring an NDR Sensor](#)
  - [Upgrading EOS or the NDR Sensor Extensions](#)
  - [Displaying NDR Sensor Information](#)
  - [NDR Sensor Commands](#)

#### 21.9.1 NDR Sensor Extension Installation

If the switch currently has the **NDRSensor.swix** installed, upgrade the EOS image or extension use the following the steps to uninstall an extension before proceeding to install a new extension. After the switch returns to an active state with a supported EOS.swi, copy and install the **NDRSensor.swix** extension.

```
switch# copy <source>/NDRSensor.swix extension:
switch# extension NDRSensor.swix
```

To show the status of extensions, use the following command.

```
switch# show extensions
Name Version/Release Status Extension

NDRSensor.swix 4.30.1F/316201\ A, NI, B 8
 29.4301F
```

Optionally, copy **NDRSensor.swix** to boot-extensions.

```
switch# copy installed-extensions boot-extensions
Copy completed successfully.
```

Refer to [Managing EOS Extensions](#) for additional details on managing extensions on EOS.

## 21.9.2 Configuration

### 21.9.2.1 SSL Profile Configuration

To configure an SSL profile for communication with the AVA Nucleus, use the following commands:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile profile-name
switch(config-mgmt-sec-ssl-profile-awake-nucleus1)# certificate certificate-name key key-name
switch(config-mgmt-sec-ssl-profile-awake-nucleus1)# trust certificate system
```

The AVA Nucleus certificate can be self-signed or signed by a third party. For the self-signed case, the certificate must be copied onto the switch **certificate:** directory and configured using the **trust certificate <certificate>** command under the **SSL profile** configuration. In case it's signed by a third party, then the CA certificate of the third party needs to be copied onto the switch **certificate:** directory and configured using **trust certificate <certificate>**. If the third-party is a common CA and is present in the system-supplied list of trusted CAs (most cases), then the **trust certificate system** can be used, and no certificate needs to be copied over to the switch.

Refer to [SSL certificate and key management](#) for additional details on all SSL profile configuration parameters.

### Generating SSL Key and Self-signed Certificate

Use these steps to set up a sensor and Nucleus SSL connection with self-signed certificates. For complete details on the EOS TLS security, refer to [EOS user manual control plane security section](#).

- To create an SSL key on the switch:

```
switch# security pki key generate rsa 2048 key-name
```

- To show the SSL key generated:

```
switch# show management security ssl key key-name
```

- To generate a self-signed certificate on the switch, use the following CLI.

```
switch# security pki certificate generate self-signed certificate-name key key-name generate
rsa 2048 [parameters ...]
```

Enter the certificate parameters interactively or use the **parameters** option to specify them inline. Once the SSL key and certificate are generated, they can be used in the **ssl profile**.

- The generated certificate needs to be copied to AVA Nucleus using either the **more** or **copy** command in the switch CLI.

```
switch# more certificate:certificate-name --> Will emit certificate on the switch console
```

```
switch# copy certificate:certificate-name destination --> To copy certificate to external
location
```

### 21.9.2.2 Configuring Monitor Security Awake

- To configure the feature, enter the Monitor Security Awake Configuration Mode:

```
switch(config)# monitor security awake
```

- To configure the maximum flow table size as 20K entries, use the following command:

```
switch(config-monitor-security-aware) # flow table size 20 entries
! The flow table size configuration change will cause the FlowWatcher agent restart and all
active flows to be lost.
Do you wish to proceed with this command? [y/N]
```

The default flow table size consists of 16,000 entries. A change in the flow table size configuration restarts the FlowWatcher Agent.

- To configure Kafka topic name as MyKafkaTopic, use the following command:

```
switch(config-monitor-security-aware) # topic MyKafkaTopic
```

Monitor Security Awake uses **packet-analysis-sessions** as the default topic name.

- To configure monitor-point identifier (MPID) to identify a campus or a site, use the following command:

```
switch(config-monitor-security-aware) # monitor-point identifier 25
```

Every NDR sensor must be configured with a unique monitor-point identifier and provisioned in the Nucleus. NDR uses 0 as the default monitor point ID.

Multiple NDR switch sensors can be configured with the same monitor point identifier.

### Displaying NDR Sensor Information

Use the **show monitor security awake** command:

```
switch# show monitor security awake
Monitor security awake status: active
Topic identifier: packet-analysis-sessions
Monitor point identifier: 0
Flow table size: 16384 entries
Flow table inactive timeout: 40.0 seconds
Active interfaces: Et37,39,49

Nucleus: nucleus1
Status: connected
VRF: default
Local interface: Management1 (172.28.134.144)
Destination: 10.243.93.139 port 9094
SSL profile: awake-nucleus1
Last established: 2 days, 19:58:23 ago
```

### 21.9.2.3 Configuring a Nucleus

- To configure the Nucleus with the name *MyNucleus*, enter the Monitor Security Nucleus Configuration Mode:

```
switch(config-monitor-security-aware) # nucleus MyNucleus
```

- To configure Nucleus IP address, 192.168.168.1, and port 9094, use the following command:

```
switch(config-monitor-security-awake-nucleus-MyNucleus)# destination 192.168.168.1 port 9094
```

The Nucleus uses port 9094 by default.

- To configure the local interface for the source IP address, use the following VRF information:

```
switch(config-monitor-security-awake-nucleus-MyNucleus)# local interface Eth1
```

- Use the following command to configure an SSL profile with the name, *MyNucleusSSL*:

```
switch(config-monitor-security-awake-nucleus-MyNucleus)# ssl profile MyNucleusSSL
```

## Configuring an SSL Profile for a Nucleus Connection

Use the following commands to configure an SSL profile, *MyNucleusSSL*, with a self-signed certificate, *MyCert*, and a key, *MyKey*, on the switch:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile MyNucleusSSL
switch(config-mgmt-sec-ssl-profile-MyNucleusSSL)# certificate MyCert key MyKey
switch(config-mgmt-sec-ssl-profile-MyNucleusSSL)# trust certificate system
```

### 21.9.2.4 Configuring a Loopback Interface

If at least one Nucleus doesn't have a local interface configured, then you must configure ***Loopback0*** interfaces with an IP address. Hardware flow tracking uses the ***Loopback0*** interface as a local interface for sending IPFIX records to the CPU.

```
switch(config)# interface Loopback0
switch(config-if-Lo0)# ip address 192.168.168.25
```

### 21.9.2.5 AVA Sensor Configuration Examples

The following steps configure an example AVA Sensor:

```
switch# Generate SSL client key
switch# security pki key generate rsa 2048 client-key
switch# show management security ssl key client-key
...
switch# Generate SSL client certificate
switch# security pki certificate generate self-signed client-cert key client-key generate rsa 2048
parameters common-name SwitchName country US state CA locality "Santa Clara" organization Arista
organization-unit IT
certificate:client-cert generated
switch# show management security ssl certificate client-cert
...
switch# Copy SSL client certificate to AVA nucleus
switch# copy certificate:client-cert <destination>

switch# Copy AVA nucleus certificate onto Switch
switch# copy terminal: certificate:ca-cert
enter input line by line; when done enter one or more control-d
...
Copy completed successfully.
switch# show management security ssl certificate ca-cert
...
Create SSL profile with client-key, client-cert and ca-cert
```

```

switch(config)# management security
switch(config-mgmt-security)# ssl profile awake-nucleus
switch(config-mgmt-sec-ssl-profile-awake-nucleus)# certificate client-cert key client-key
switch(config-mgmt-sec-ssl-profile-awake-nucleus)# trust certificate ca-cert
switch(config-mgmt-sec-ssl-profile-awake-nucleus)# end

Enable IP routing
switch# conf
switch(config)# ip routing

Configure monitor security awake and enable
switch(config)# monitor security awake
switch(config-monitor-security-awake)# monitor-point identifier 1
switch(config-monitor-security-awake)# nucleus awake-nucleus
switch(config-monitor-security-awake-nucleus-awake-nucleus)# local interface Management 1
switch(config-monitor-security-awake-nucleus-awake-nucleus)# destination nucleus1.foo.com
switch(config-monitor-security-awake-nucleus-awake-nucleus)# ssl profile awake-nucleus
switch(config-monitor-security-awake-nucleus-awake-nucleus)# exit
switch(config-monitor-security-awake-nucleus-awake-nucleus)# no disabled
switch(config-monitor-security-awake-nucleus-awake-nucleus)# end

```

Display the running configuration:

```

...
management security
 ssl profile awake-nucleus
 certificate client-cert key client-key
 trust certificate ca-cert
...
ip routing
...
monitor security awake
 nucleus awake-nucleus
 local interface Management1
 destination nucleus1.foo.com
 ssl profile awake-nucleus
 no disabled

```

A sample configuration output with multiple profiles and Nucleus on a switch

```

management security
 ssl profile awake-nucleus1
 certificate client-cert key client-key1
 trust certificate system
 ssl profile awake-nucleus2
 certificate client-cert key client-key2
 trust certificate root-cert2

monitor security awake
 topic packet-analysis-sessions
 monitor-point identifier 10
 flow table size 153600 entries
!
nucleus nucleus1
 local interface Loopback10
 destination nucleus1.network.com
 ssl profile awake-nucleus1
nucleus nucleus2
 local interface Management1
 destination nucleus2.network.com
 ssl profile awake-nucleus2
no disabled

```

### 21.9.3 Upgrading EOS and/or **NDRSensor.swix** Extension

1. Disable the AVA sensor by configuring **disabled** under **monitor security awake**. This stops the AVA switch sensor running on the switch.
2. Uninstall **NDRSensor.swix** extension.

```
switch# show installed-extensions
```

```
NDRSensor.swix

switch# no extension NDRSensor.swix
switch# show extensions
Name Version/Release Status Extension

NDRSensor.swix 4.30.1F/316201\ A, NI, B 8
 29.4301F
```

**3. Remove **NDRSensor.swix** from boot extensions.**

```
switch# show boot-extensions
NDRSensor.swix # Old extension needs to be removed from boot-extension

switch# copy installed-extensions boot-extensions
Copy completed successfully.

switch# show boot
boot-extensions empty.
```

- 4. Upgrade the EOS image on the switch - Follow the steps to upgrade the EOS image on the device as described in the EOS Configuration Guide.**
- 5. Install the new **NDRSensor.swix** extension corresponding to the new EOS image and copy it to boot-extensions. This step is the same as in the [NDR Sensor Extension Installation](#).**
- 6. Verify the AVA switch sensor as running by using the **show monitor security awake** command.**

## 21.9.4 Show Commands

- The following CLI command display the status of the Monitor security Awake feature:

```
switch# show monitor security awake [nucleus <nucleus>]
```

### Example

```
switch# show monitor security awake
Monitor security awake status: active
Topic identifier: packet-analysis-sessions
Monitor point identifier: 0
Flow table size: 16384 entries
Flow table inactive timeout: 40.0 seconds
Active interfaces: Et37,39,49

Nucleus: nucleus1
Status: connected
VRF: default
Local interface: Management1 (172.28.134.144)
Destination: 10.243.93.139 port 9094
SSL profile: awake-nucleus1
Last established: 2 days, 19:58:23 ago
```

- The following CLI command shows the various counters of the Monitor security awake feature:

```
switch# show monitor security awake counters [flows|ipfix|nucleus [<nucleus>]]
```

### Example

```
switch# show monitor security awake counters
Active flows: 269, RX packets: 8.943M (8943077)
Flows created: 558.655K (558655), expired: 558.386K (558386)

IPv4 flows:
Application Flows Active Flows Created Flows Expired

Flow record queue full: 0

```

- The following CLI command shows the flow table snapshot of all the flows currently active in the FlowWatcher agent:

```
switch# show monitor security awake flow-table [detail]
```

Use the following debugging command and create a snapshot of the current flow table.

### Example

```

switch# show monitor security awake flow-table
IPv4 flows: 5
Lower IP address Higher IP address Protocol Start Time Packets
Bytes

10.8.3.102:58119 87.98.179.150:6893 UDP 2022-03-09 21:54:00.447260 1

```

## 21.9.5 Limitations

- **NDRSensor.swix** is supported on 32-bit and 64-bit EOS versions.
- In an MLAG setup, the AVA switch sensor does not correlate bidirectional flows hashed to different MLAG peers.
- AVA switch sensor doesn't correlate bidirectional flows using NAT.
- After enabling the AVA switch sensor, the TerminAttr agent also processes IPFIX packets sent to the CPU, and automatically enables the Traffic flows feature on the CloudVision portal which can cause additional CPU usage on the switch. If you do not require traffic flow on CloudVision, disable TerminAttr IPFIX processing by adding the **-ipfix=false** argument to **exec /usr/bin/TerminAttr** under the **daemon TerminAttr** configuration.

## 21.9.6 AVA Sensor Commands

- [monitor security awake](#)
- [show monitor security awake](#)
- [show monitor security awake counters](#)

### 21.9.6.1 monitor security awake

When the **monitor security awake** command is enabled the FlowWatcher agent enables Hardware flow tracking with filter-based packet sampling, IP/IPv6 access lists, and mirroring features to receive the first few packets of every new flow and flow volume using IPFIX.

The **no** form of the **monitor security awake** command disables the **monitor security awake** feature from the **running config**.

**Note:** Before enabling the **monitor security awake** command, you must have install the **NDRSensor.swix** extension on the system running a supported EOS version.

#### Command Mode

Global Configuration

#### Command Syntax

```
monitor security awake
```

---

```
no monitor security awake
default monitor security awake
```

### Example

These commands create and enable a non-persistent DirectFlow flow.

```
switch(config)# monitor security awake
switch(config-monitor-security-aware)#
```

## 21.9.6.2 show monitor security awake

The **show monitor security awake** command displays the status of the Monitor Security Awake feature on the switch.

### Command Mode

EXEC

### Command Syntax

```
show monitor security awake [nucleus nucleus]
```

### Parameters

- **nucleus *nucleus*** - Specify the Nucleus name to display information.

### Example

This command displays the status of the Monitor security Awake feature on the switch.

```
switch# show monitor security awake
Monitor security awake status: active
Topic identifier: packet-analysis-sessions
Monitor point identifier: 0
Flow table size: 16384 entries
Flow table inactive timeout: 40.0 seconds
Active interfaces: Et37,39,49

Nucleus: nucleus1
Status: connected
VRF: default
Local interface: Management1 (172.28.134.144)
Destination: 10.243.93.139 port 9094
SSL profile: awake-nucleus1
Last established: 2 days, 19:58:23 ago
```

## 21.9.6.3 show monitor security awake counters

The **show monitor security awake counters** command displays the various counters of the Monitor Security Awake feature on the switch.

### Command Mode

EXEC

### Command Syntax

```
show monitor security awake counters [flows | ipfix | nucleus nucleus]
```

### Parameters

- **flows** - Displays information about flow counters.
- **ipfix** - Displays information about IPFIX counters.
- **nucleus nucleus** - Displays counters for a specified nucleus.

### Example

This command displays the various counters of the Monitor Security Awake feature on the switch.

```
switch# show monitor security awake counters
Active flows: 269, RX packets: 8.943M (8943077)
Flows created: 558.655K (558655), expired: 558.386K (558386)

IPv4 flows:
Application Flows Active Flows Created Flows Expired
----- -----
DHCP 9 13.072K (13072) 13.063K (13063)

```

## 21.10 Connectivity Monitor

Connectivity Monitor provides unidirectional monitoring of network resources from an Arista switch. The monitored resources may or may not be Arista devices. In this section, all Connectivity Monitor commands have documentation for configuring the feature from the CLI. To configure the feature using a GUI, see the [CloudVision Help Center Connectivity Monitor](#) documentation.

### 21.10.1 Connectivity Monitor Command Reference

#### Global Configuration Commands

- [monitor connectivity](#)
- [monitor connectivity icmp count](#)
- [monitor connectivity icmp echo](#)

- 
- monitor connectivity interface
  - monitor connectivity interval
  - monitor connectivity local-interfaces
  - monitor connectivity loss-threshold
  - monitor connectivity name-server
  - monitor connectivity shutdown

### **Client Configuration Commands**

- client host
- client icmp count
- client icmp echo
- client interval
- client loss-threshold
- client name-server
- monitor connectivity client

### **Host Configuration Commands**

- host icmp count
- host icmp echo
- host ip
- host local-interfaces
- host name-servers
- host tcp
- host url
- monitor connectivity host
- no icmp echo

### **VRF Configuration Commands**

- monitor connectivity vrf
- vrf description
- vrf host
- vrf interface
- vrf local-interfaces

### **Show Commands**

- show monitor connectivity

#### **21.10.1.1 client host**

The **monitor connectivity client host** command configures clients to accept connectivity probes from a host.

##### **Command Mode**

Monitor Connectivity Client Configuration Mode

Monitor Connectivity VRF Configuration Mode

##### **Command Syntax**

```
monitor connectivity [client client_name | vrf vrf_name] host host_name
```

## Parameters

**host *host\_name*** - Specify a host to send connectivity probes to the client.

### Example

Use the following commands to configure a host, *cloudserver*, to send connectivity probes to a client, *MyClient*:

```
switch(config) # monitor connectivity
switch(config-mon-connectivity) # client MyClient
switch(config-mc-client-MyClient) # host cloudserver
```

Use the following commands to configure a VRF, *purple*, to send connectivity probes to a VRF, *MyVRF*:

```
switch(config) # monitor connectivity
switch(config-mon-connectivity) # vrf purple
switch(config-mc-vrf-purple) # host cloudserver
```

## 21.10.1.2 client interval

The **client interval** command configures the interval between probes on a client. By default, EOS sets the interval to 10 seconds.

### Command Mode

Connectivity Monitor Client Configuration Mode

### Command Syntax

**client interval *interval***

### Parameters

**interval *interval*** - Configure the interval between probes as a value between 1 and 65535 seconds. EOS has a default value of 10 seconds.

### Example

Use the following command to set the interval between probes to 60 seconds on *MyClient*:

```
switch(config-mon-connectivity) # client MyClient
switch(config-mc-client-myClient) # interval 60
```

## 21.10.1.3 client loss-threshold

The **client loss-threshold** command configures the sequential lost probe count threshold on a client.

### Command Mode

---

Connectivity Monitor Client Configuration Mode

#### Command Syntax

```
client loss-threshold count probes
```

#### Parameters

**loss-threshold count** - Configure the sequential lost probe threshold as a value between 1 and 65535 probes. EOS has a default value of 10 seconds and uses **probes** as a unit.

#### Example

Use the following command to set the sequential lost probe threshold to 60 seconds on *MyClient*:

```
switch(config-mon-connectivity)# client MyClient
switch(config-mc-client-myClient)# loss-threshold 60 probes
```

### 21.10.1.4 host description

The **host description** command configures a brief description of the host.

#### Command Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor VRF Configuration Mode

#### Command Syntax

```
host description description
vrf description description
```

#### Parameters

**description description** - Configure a description for the host or VRF.

#### Example

Use the following command to configure a description *Remote-Host Rack 12 myHost*:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# description Remote-Host Rack 12
```

Use the following command to configure a description *VRF-remote 12 myVRF*:

```
switch(config-mon-connectivity)# vrf MyVRF
switch(config-mc-vrf-MyVRF)# description VRF-remote
```

### 21.10.1.5 host ip

The **host ip** command configures the endpoint for ICMP probing on the host.

## Command Mode

Connectivity Monitor Host Configuration Mode

## Command Syntax

```
host ip [ipv4_address | ipv6_address] [hostname host_name resolution [ipv4 | ipv6]]
```

## Parameters

- **ip** - Specify the IP address for the endpoint as IPv4 or IPv6.
  - ***ipv4\_address*** - Specify the IPv4 address in dotted decimal notation.
  - ***ipv6\_address*** - Specify the IPv6 address in colon separated notation.
- ***hostname host\_name*** - Specify the host name to resolve to the endpoint.
- **resolution** - Specify the preferred IP address family as IPv4 or IPv6
  - ***ipv4***
  - ***ipv6***

### Example

Use the following command to configure the endpoint as an IPv4 address, 172.16.21.25, on the host, *myHost*:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# ip 172.16.21.25
```

## 21.10.1.6 host tcp

The **host tcp** command configures a TCP probe for Connectivity Monitoring. When enabled, Connectivity Monitoring measures the total round trip time of a TCP 3-way handshake. The **no** version of this command disables the configuration and removes it from the ***running-config***.

## Command Mode

Connectivity Monitor Host Configuration Mode

## Command Syntax

```
host ip [ipv4_address | ipv6_address] tcp port port_number resolution [ipv4 | ipv6]]
```

## Parameters

- **ip** - Specify the IP address for the endpoint as IPv4 or IPv6.
  - ***ipv4\_address*** - Specify the IPv4 address in dotted decimal notation.
  - ***ipv6\_address*** - Specify the IPv6 address in colon separated notation.
- ***hostname host\_name*** - Specify the host name to resolve to the endpoint.
- **resolution** - Specify the preferred IP address family as IPv4 or IPv6
  - ***ipv4***
  - ***ipv6***
- ***tcp port port\_number*** - Specify TCP and a port number between 0 and 65535

### **Example**

Use the following command to configure the IPv4 address, 172.16.21.25 with TCP and port 80:  
*myHost*:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# ip 172.16.21.25
switch(config-mc-host-myHost)# tcp port 80
```

## **21.10.1.7 host url**

The **host url** command configures a URL for the host.

### **Command Mode**

Connectivity Monitor Host Configuration Mode

### **Command Syntax**

```
host url url
```

### **Parameters**

**url** *url* - Configure a URL for the host.

### **Example**

Use the following command to configure a URL, *https://172.16.21.1* for the host, *myHost*:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# url https://172.16.21.1
```

## **21.10.1.8 monitor connectivity**

The **monitor connectivity** command enters the Connectivity Monitor Configuration Mode on a switch.

### **Command Mode**

Global Configuration Mode

### **Command Syntax**

```
monitor connectivity
```

### **Example**

Use the following command to enter Connectivity Monitor Configuration Mode:

```
switch(config)# monitor connectivity
```

```
switch(config-mon-connectivity) #
```

### 21.10.1.9 monitor connectivity client

The **monitor connectivity client** command enters the Connectivity Monitor Client Configuration Mode on a switch.

#### Command Mode

Connectivity Monitor Configuration Mode

#### Command Syntax

```
monitor connectivity client client_name
```

#### Example

Use the following command to enter Connectivity Monitor Client Configuration Mode and add a client *MyClient*:

```
switch(config) # monitor connectivity
switch(config-mon-connectivity) # client MyClient
switch(config-mc-client-MyClient) #
```

### 21.10.1.10 monitor connectivity description

The **monitor connectivity description** command configures a brief description of the host or VRF.

#### Command Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor VRF Configuration Mode

#### Command Syntax

```
host host_name description description
vrf vrf_name description description
```

#### Parameters

**description *description*** - Configure a description for the host or VRF.

#### Examples

Use the following command to configure a description *Remote-Host* of the host, *myHost*:

```
switch(config-mon-connectivity) # host myHost
switch(config-mc-host-myHost) # description Remote-Host
```

Use the following command to configure a description *Remote-VRF* of the VRF *purple*:

```
switch(config-mon-connectivity)# vrf purple
switch(config-mc-vrf-purple)# description Remote-VRF
```

### 21.10.1.11 monitor connectivity icmp echo qos dscp

The **monitor connectivity icmp echo qos dscp** command configures DSCP bit on a host or client to classify and manage network traffic such as prioritizing packets when network congestion occurs.

#### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor Client Configuration Mode

#### Command Syntax

```
icmp echo qos dscp dscp_value
client client_name icmp echo qos dscp dscp_value
[host host_name | client client_name] icmp echo qos dscp dscp_value
```

#### Parameters

- **host *host\_name*** - Configure the host name.
- **client *client\_name*** - Configure the client name.
- **icmp echo qos dscp** - Set the DSCP value in the IP header.

#### Examples

Use the following command to globally set the ICMP echo to use a DSCP value of *af11*:

```
switch(config-mon-connectivity)# icmp echo qos dscp af11
```

Use the following command to set the ICMP echo to use a DSCP value of *af11* on *myHost*:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# icmp echo qos dscp af11
```

Use the following command to set the ICMP echo to use a DSCP value of *af11* on *MyClient*:

```
switch(config-mon-connectivity)# client MyClient
switch(config-mc-client-MyClient)# icmp echo qos dscp af11
```

### 21.10.1.12 monitor connectivity host

The **monitor connectivity host** command enters the Connectivity Monitor Host Configuration Mode on a switch.

#### Command Mode

Connectivity Monitor Configuration Mode

### Command Syntax

```
monitor connectivity host host_name
```

#### Example

Use the following command to enter Connectivity Monitor Host Configuration Mode and add a host *MyHost*.

```
switch(config) # monitor connectivity
switch(config-mon-connectivity) # host MyHost
switch(config-mc-host-MyHost) #
```

## 21.10.1.13 monitor connectivity icmp

The **monitor connectivity icmp** command configures ICMP ping parameters globally, on a host, or a client.

### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor Client Configuration Mode

### Command Syntax

```
icmp count ping_count
client client_name] icmp count ping_count
host host_name icmp count ping_count
```

### Parameters

- **host *host\_name*** - Configure the host name.
- **client *client\_name*** - Configure the client name.
- **icmp count *ping\_count*** - Configure the ping count between 1 and 100. EOS sets the ping count to five (5) by default.

#### Examples

Use the following command to set the ping count to 10 globally:

```
switch(config-mon-connectivity) # icmp count 10
```

Use the following command to set the ping count to 10 on *MyClient*:

```
switch(config-mon-connectivity) # client MyClient
switch(config-mc-client-MyClient) # icmp count 10
```

---

Use the following command to set the ping count to 10 on *myHost*:

```
switch(config-mon-connectivity) # host myHost
switch(config-mc-host-myHost) # icmp count 10
```

#### 21.10.1.14 monitor connectivity icmp count

The **monitor connectivity icmp count** command configures ICMP ping parameters globally, on a host, or a client.

##### Command Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor Client Configuration Mode

##### Command Syntax

```
icmp count ping_count
client client_name icmp count ping_count
host host_name] icmp count ping_count
```

##### Parameters

- **host host\_name** - Configure the host name.
- **client client\_name** - Configure the client name.
- **icmp count ping\_count** - Configure the ping count between 1 and 100. EOS sets the ping count to five (5) by default.

##### Examples

Use the following command to globally set the ping count to 10:

```
switch(config-mon-connectivity) # icmp count 10
```

Use the following command to set the ping count to 10 on *MyClient*:

```
switch(config-mon-connectivity) # client MyClient
switch(config-mc-client-MyClient) # icmp count 10
```

Use the following command to set the ping count to 10 on *myHost*:

```
switch(config-mon-connectivity) # host myHost
switch(config-mc-host-myHost) # icmp count 10
```

### 21.10.1.15 monitor connectivity icmp echo

The `monitor connectivity icmp echo` command configures DSCP bit on a host or client to classify and manage network traffic such as prioritizing packets when network congestion occurs.

#### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor Client Configuration Mode

#### Command Syntax

```
icmp echo qos dscp dscp_value
client client_name icmp echo qos dscp dscp_value
host host_name icmp echo qos dscp dscp_value
```

#### Parameters

- `host host_name` - Configure the host name.
- `client client_name` - Configure the client name.
- `icmp echo qos` - Configure ICMP QoS parameters.
- `dscp dscp_value` - Set the DSCP value in the IP header.

#### Examples

Use the following command to globally set the ICMP echo to use a DSCP value of `af11`:

```
switch(config-mon-connectivity)# icmp echo qos dscp af11
```

Use the following command to set the ICMP echo to use a DSCP value of `af11` on `myHost`:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# icmp echo qos dscp af11
```

Use the following command to set the ICMP echo to use a DSCP value of `af11` on `MyClient`:

```
switch(config-mon-connectivity)# client MyClient
switch(config-mc-client-MyClient)# icmp echo qos dscp af11
```

### 21.10.1.16 monitor connectivity interface

The `monitor connectivity interface` command configures a collection of interfaces used as a source interface for probing.

#### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor VRF Configuration Mode

#### Command Syntax

---

```
interface set set_name [Dps | Ethernet | Fabric | InternalRecirc | Loopback | Management | Port-Channel | Recirc-Channel | Tunnel | Vlan | Vxlan] interface
vrf vrf_name interface set set_name [Dps | Ethernet | Fabric | InternalRecirc | Loopback | Management | Port-Channel | Recirc-Channel | Tunnel | Vlan | Vxlan] interface
```

## Parameters

**interface set *set\_name*** - Configure an interface set using the following interfaces:

- **Dps**
- **Ethernet**
- **Fabric**
- **InternalRecirc**
- **Loopback**
- **Management**
- **Port-Channel**
- **Recirc-Channel**
- **Tunnel**
- **Vlan**
- **Vxlan**

### Example

Use the following command to configure an interface set, *source\_probe*, and the interfaces, *Ethernet1*, *Ethernet2*:

```
switch(config-mon-connectivity)# interface set source_probe Ethernet 1, Ethernet2
```

Use the following command to configure an interface set, *source\_probe*, and the interfaces, *Ethernet1*, *Ethernet2* on VRF *purple*:

```
switch(config-mon-connectivity)# vrf purple
switch(config-mc-vrf-purple)# interface set source_probe Ethernet 1, Ethernet2
```

## 21.10.1.17 monitor connectivity interval

The **monitor connectivity interval** command configures the interval between probes globally or on a client.

### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor Client Configuration Mode

### Command Syntax

**interval *count***

**client *client\_name* interval *count***

## Parameters

**interval *count*** - Configure the probe interval as a value between 1 and 65535 probes. EOS has a default value of 10 seconds.

### Examples

Use the following command to set the probe interval to 60 seconds globally>:

```
switch(config-mon-connectivity) # interval 60
```

Use the following command to set the probe interval to 60 seconds on *MyClient*:

```
switch(config-mon-connectivity) # client MyClient
switch(config-mc-client-myClient) # interval 60
```

## 21.10.1.18 monitor connectivity local-interfaces

The **monitor connectivity local-interfaces** command configures the default interface set for ICMP probing globally, on the host, or on a VRF. The **default** version of the command applies only to the global configuration. In the Connectivity Monitor Configuration Mode, the **default** parameter selects an existing interface set to use as the default interface set for probing in the ICMP mode.

### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor Host Configuration Mode

Connectivity Monitor VRF Configuration Mode

### Command Syntax

```
local-interfaces interface_sets address-only default
[host host_name local-interfaces interface_sets address-only default
vrf vrf_name local-interfaces interface_sets address-only default
```

### Parameters

- **host *host\_name*** - Specify the name of the host to apply the interface sets.
- **local-interfaces *interface\_sets*** - Specify the name of the interface sets.
- **address-only** - Specify using the interface sets for the source addresses only. Use this command in the Connectivity Monitor Host Configuration Mode. This sets the source IP address to the IP configured on the interface. If not configured, the probes send packets directly from the interface.
- **default** - Configure the interface set as the default. Use this parameter in the Connectivity Monitor Configuration Mode only.

### Examples

Use the following command to globally configure the interface set, *MyLocalInterfaces* as the default interface set:

```
switch(config-mon-connectivity)# local-interfaces MyLocalInterfaces
default
```

Use the following command to configure the interface sets, *MyLocalInterfaces* on the host, *myHost*:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# local-interfaces MyLocalInterfaces
```

Use the following command to configure the interface sets, *MyLocalInterfaces* on the VRF, *purple*:

```
switch(config-mon-connectivity)# vrf purple
switch(config-config-mc-vrf-purple)# local-interfaces MyLocalInterfaces
```

### 21.10.1.19 monitor connectivity loss-threshold

The **monitor connectivity loss-threshold** command configures the sequential lost probe count threshold globally or on a client.

#### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor Client Configuration Mode

#### Command Syntax

```
loss-threshold count probes
client client_name loss-threshold count probes
```

#### Parameters

- **client *client\_name*** - Configure the name of the client.
- **loss-threshold *count*** - Configure the sequential lost probe threshold as a value between 1 and 65535 probes. EOS has a default value of 10 seconds.

#### Example

Use the following command to globally set the sequential lost probe threshold to 60 seconds:

```
switch(config-mon-connectivity)# 60 probes
```

Use the following command to set the sequential lost probe threshold to 60 probes on *MyClient*:

```
switch(config-mon-connectivity)# client MyClient
switch(config-mc-client-myClient)# 60 probes
```

### 21.10.1.20 monitor connectivity name-server

The **monitor connectivity name-server** command configures the IP address of a DNS name server on a host or a client to resolve hostnames. The **no** version of the command disables the configuration.

#### Command Mode

Connectivity Monitor Configuration Mode

Connectivity Monitor Client Configuration Mode

Connectivity Monitor Host Configuration Mode

#### Command Syntax

```
name-server group group_name
client client_name name-server group group_name
| host host_name name-server group group_name
```

#### Parameters

- **client *client\_name*** - Configure the host name.
- **host *host\_name*** - Configure the client name.
- **name-server group *group\_name*** - Configure name of the DNS name server.

#### Examples

Use the following command to globally set the name server to *myDNSServer*:

```
switch(config-mon-connectivity)# name-server myDNSServer
```

Use the following command to set the name server to *myDNSServer* on *MyClient*:

```
switch(config-mon-connectivity)# client MyClient
switch(config-mc-client-MyClient)# name-server myDNSServer
```

Use the following command to set the name server to *myDNSServer* on *myHost*:

```
switch(config-mon-connectivity)# host myHost
switch(config-mc-host-myHost)# name-server myDNSServer
```

### 21.10.1.21 monitor connectivity shutdown

The **monitor connectivity shutdown** command shuts down connectivity monitoring on the switch.

#### Command Mode

Connectivity Monitor Configuration Mode

#### Command Syntax

```
shutdown
```

#### Parameters

**shutdown** - Shut down connectivity monitoring on the switch

### Example

Use the following command to shutdown connectivity monitoring on the switch:

```
switch(config-mon-connectivity) # shutdown
```

## 21.10.1.22 monitor connectivity vrf

The **monitor connectivity vrf** command to configure a specific VRF to use default probing for hosts. Hosts configured globally use the default VRF.

### Command Mode

Connectivity Monitor Configuration Mode

### Command Syntax

```
monitor connectivity vrf vrf_name
```

### Parameters

**vrf *vrf\_name*** - Configure a VRF for hosts to use for probing.

### Example

Use the following command to configure a VRF, *purple*, for connectivity monitoring on the switch:

```
switch(config-mon-connectivity) # vrf purple
```

## 21.10.1.23 no icmp echo

The **no icmp echo** command disables ICMP probes on the switch. Since TCP and ICMP share the same probing endpoint, it may be desirable to shut down ICMP while using TCP probes.

### Command Mode

Connectivity Monitor Host Configuration Mode

### Command Syntax

```
no icmp echo disabled
```

### Parameters

- **host *host\_name*** - Configure the host name.
- **icmp echo disabled** - Disables ICMP probing on the host.

### Examples

Use the following command to disable ICMP probing on host *myHost*:

```
switch(config-mon-connectivity) # host myHost
switch(config-mc-host-myHost) # no icmp echo disabled
```

### 21.10.1.24 show monitor connectivity

The **show monitor connectivity** command displays information about the Connectivity Monitor status and configuration on the switch. Display statistics for all configured hosts or a specific host.

#### Command Mode

EXEC

#### Command Syntax

```
show monitor connectivity [host host_name]
```

#### Parameters

**host *host\_name*** - Specify the host to display information about Connectivity Monitor.

#### Examples

Use the following command to display information about all configured hosts for Connectivity Monitor:

```
switch# show monitor connectivity
VRF: default
Host: h1
HTTP statistics:
http://myhomesite.com
 Local Interface Response Time

 Ethernet31/1 2.444ms
